Sorry Wim, I can't agree with some of your statements in your last post. Concerning maximum output, I will agree that saturation will occur when the minimum of the peak AC plate voltage equals the peak AC grid voltage. This condition occurs when the tube is delivering its total maximum possible power. However, when the grid drive level is less than that which brings the plate-voltage minimum down to the grid-voltage level, saturation does not occur.

In addition, when the pi-network has been adjusted to deliver all the available power at some drive level less than the maximum possible power, the source resistance at the output of the pi-network will be exactly equal to its load resistance, not somewhat higher or lower. This follows from the Maximum Power Transfer Theorem. This is not speculation, but proof determined by data from many, many measurements.

That's not necessarily true. I have some RG-59 cables with male 75 ohm BNC connectors that mate fine with 50 ohm connectors. The diameter of the 75 ohm connector center pin is the same diameter as 50 ohm connectors. The difference is that the dielectric surrounding the center pin of the 75 ohm connector is much thinner. And at the point where the pin enters the solid dielectric at the bottom, the 75 ohm pin doesn't step up in diameter.

Others have said that there are some 75 ohm BNC connectors which won't interconnect without damage. But I do know there are some that mate with no problem. 50 ohm BNC connectors and adapters are very common. I suggest you get one and compare the center pin diameter with that of your 75 ohm connector. If it's the same, the two can interconnect without damage.

I also have a lot of RG-59 cables with 50 ohm BNC connectors. That's probably more common, since 50 ohm connectors are much more common, and the connector choice won't make any practical difference in the vast majority of applications.

Please support that allegation with evidence.

What are the specified diameters of the inner conductor mating surfaces
of 75R and 50R BNC plugs ?

Include allowable manufacturing tolerances, and quote your sources.

Hi Wimpie,

This is not what I asked for. You said what the source was NOT, but
you cannot say what the source IS.

The source is not a bipedal reptile. The source is not an elongated
diphthong. The source is not the resurrection of a deity (some may
argue that more than I would care to follow). The source is not....

There are many ways to say what the source is NOT, and that will never
inform us about the source. I see many draw deuces to this question
and try to convince everyone that the card is a pair of winning aces.

>Now make some mismatch (for example VSWR=2 at different phase) and
>read the forward power. Did it change? If so, the output impedance is
>no (longer) 50 Ohms.

What IS it now? If you could measure it once, you should be able to
tell us what it is this time too. I did this for years to methods set
by the National Bureau of Standards. You have drawn a deuce, not two
aces.

>Measuring method used: change in resistive load, from voltage change
>you can calculate the current change, hence the output impedance. One
>note, except two, all where solid state.

Yes, that is called a load pull, but you offer no data - another
deuce. I have done a lot of load pulls.

>All high efficiency designs (class E, D) that I did have output
>impedance far from the expected load impedance. With "far" I mean >
>factor 2 or < factor 0.5. I did not measure that (as it is not
>important in virtually all cases), but know it from the overload
>simulation/measurement and I did the design myself.

You didn't measure it, but you can state the value - interesting state
of guessing. So, what did the simulation/non-measurement give you as
a value? What IS the value? Another deuce.

>The reason for not being 50 Ohms

Reasons abound. BP is giving us reasons why the Gulf Coast shouldn't worry. Data has proven that reasons don't work and neither does their well. That is a Joker draw.

>High efficiency CW amplifiers

The TS830S is not such an animal. Another Deuce.

Just a minor note, but coaxial cable Arcnet connectors, using 93 ohm
RG-62a/u coax cable, also used 50 ohm BNC connectors. The terminators
were 93 ohm resistors inside 50 ohm BNC connectors:

I have no problem with your view point and it is something I am
concerned about. Since I have followed this path however, every thing
is meshing
and I am reporting it as I do not fear failure. But to my mind I have
not hit anything to cause me to give up. On top of that nobody has
raised any particular points of discussion either. Remember it took me
years to convince all that extending Gauss
was OK and it provided arrays where all elements were resonant each of
which can be fed. So I was right there and everybody else was in
error, relying on books only and not there own education.
Now I am spreading my wings based on what the former has shown and
will re evaluate again when done. At each time I will continue to
share results
even if it finally shows some errors But I certainly will not stop
because of intuitions from the group which up to now has been proved
wrong. Nothing wrong with following the teachings of the books as
followers but I am attempting to be a leader in finding truths about
radiation. So far I have proved the presence of particles, realised
equilibrium in every way and now I appear to be proving that skin
depth is not a constant. A lot of work to do but as an engineer I knew
it would take a while and on top of that I supplied it to a academic
to break it down
as one always should get an independent evaluation. So far every thing
that Einstein predicted has shown up in my workings such that if he
had seen it there would have been no need for alternate physics

proposals, not that they were without success. The final point is that it is accepted that the machinations of radiation have not yet been proven and so far following thru with classical physics has provided with interesting view points that oppose the present teachings. So I am a fool to place my engineering experience in search of the truth where others may be happy as things are.
So I am different from the rest and what is so bad about that? It is for the group to show that I am inadequate from my aproach and to this point all
that has been presented has been proven false and I still prevail. I yearn for closure which could come from those really interested in the outcome. But at the same time in their absence I will carry on.
Future info will be on the new thread since this one is now dead and placed in the archives.

Hello Walt,

I think the problem is in the initial conditions that we use as
starting point. Your starting point is matched to maximum power output
in all cases, also under bad antenna VSWR. My starting point was a
fixed tuned amplifier, made for 50 Ohms and experiencing large
mismatch (50W reflected, 100W forward).
>
> Sorry Wim, I can't agree with some of your statements in your last

> voltage level, saturation does not occur.

In that case the final tube will more or less behave like a current
source (LF appraoch, there will be feedback via capacitance), so the
impedance will change from the value for maximum power.

There are two saturation conditions: voltage saturation, this lowers
the plate impedance, current saturation (below maximum voltage swing),
this increases the plate impedance (especially for pentodes).

We start with a maximim power matched situation (so ZL = Zout) and
don't touch the tuning.
When you now change the load (for example VSWR =2), you will probably
have a strong voltage saturation condition or strong current
saturation condition, so voltage source or current source behavior
dictates, but not both. Therefore the output impedance at the plate
will rise (current saturation) or decrease (voltage saturation). For
triodes the effect is less then for pentodes as the transition for
current saturation to voltage saturation is relatively smooth for
triodes.

Fully agree with this, but is this always the case under practical
circumstance?

When you change one of the paramers (drive level or VSWR, but not the matching), you will divert from the optimum setting, hence impedance will change. You can try the VSWR dependence by measuring the forward power under varying VSWR. I am sure it will change (keeping drive level and pi filter matching the same).

Most solid state amplifiers do not have the possibility of matching when you change VSWR, so with bad VSWR, you will be in the current or voltage saturating range of the active device and your output impedance will change.

Virtually all high efficient amplifiers work in voltage saturated mode and are therefore not operated at maximum available power, therefore their output impedance doens't match the expected load.

Except for CW, most SSB amplifiers run in the current saturated mode (so below maximum voltage swing), so they do not work at their maximum power point given the instantaneous drive level (or you need to modulate your supply also).

In real world the situation is more complex because of phase changes in VSWR and parasitic feedback that may change the gain of the active device (worst case spoken, you may get instability). I discovered (when I was younger) that with a class C fixed tuned amplifier, small changes in VSWR resulted in change of forward power, but significant change in DC supply current (and heatsink temperature). So what happens with the reflected power depends on many factors.

Of course, since the source impedance may be anywhere in the complex
plane, you need to change more than just the resistive part of the
load, I believe, to get an accurate picture...
>

What I've seen in similar situations is that the source impedance is
likely to be strongly reactive, depending on the filter network you
use to get sinusoidal output. In any event, the source impedance is
likely to have a reflection coefficient magnitude that is quite close
to unity. That is exactly what you should expect: there's nothing to
absorb reflections. You could (theoretically at least) use feedback
to make the output look like 50 ohms, but just as you say, Wim ...
why?? There's really almost never any point in doing so.

...

Cheers,
Tom

Hi folks, good night (from here).

> I do not disagree with anything you have written, but I do think it
> is much too early to introduce Poynting vectors and lossy conductors
> to the discussion.

Hello Keith, Yes, I understand your comment, I introduced Poynting vector only because both, energy and power, are scalars and we can not talk about scalars having direction without get in conceptual troubles; flux of power instead, have direction because surface vector presence in its definition gives directive characteristics to power crossing an imaginary surface.
Slanted flux of electromagnetic power (Poynting) due resistive conductor simply seems to me a good example of a power flux in a TL not totally coincident with axial direction to provide a little more supporting to "directive" notion of Power Flux.
However IMHO power flux do not seems to me more complicated than power, work, voltage, potential, energy, E and H fields, etc. All of them -I believe- are not very simple stuff :>(, but they are very funny and interesting, indeed...!! :>D. What do you think?
.....
Please would you mind tell me why "sine wave" it is not a correct use of "wave" word. The only dictionary I have => "Oxford advanced english dictionary of current english defines wave as: "move to and fro, up and down", I believe also in english there are word qualifiers (sine, traveling, standing, etc) who specify the precise meaning of them in diverse contexts. Am I wrong about this?.
....
Sorry by my insistence about convenience of discuss about "models". Please let me bring a citation:
"At times, two quite differents models may serve equally well, but eventually one is usually found to prevail, not because it is right, but because it is both more convenient and more logically constructed. After all, models are constructed for convenience in thinking and recording, not as photographic images of nature"
(From "Electromagnetic Engineering", Ronold W.P. King (PhD), page 94. McGraw Hill.1946).
....
I studied "Principle of Conjugates Impedance Matching" in my early student days and the "mirror reflection" explained by Walter Maxwell in his article agree with my undestanding about "where the reflected waves go" because to balance magnitudes it is necessary that they found a full mismatch on its way (path?) to generator. My own limited analisis led me to the same notion even without conjugate match if I calculate Incident and reflected voltages values in a half wave TL (as my early thread example),
As I said, reading Cecil's web page quarter wave line examples led me to considerate another possible representations of the problem, in addition Owen's own ideas about it also made me consider the issue from another point of view.

Thank you very nuch.

Well, we will see in a couple of weeks what I get. I broke down and bought a set consisting of a BNC crimping tool, a wire stripper and 50 rg-59 BNC plugs from an eBay store.

They did not have any rg-6 plugs, so I'm hoping that the RG6-QS I've got works.

It's the heavy duty kind that looks like a heavy duty side crimp tool, except that the wire goes in the top and the plug is pushed together from the handle end (bottom).

I'll report back.

Thanks for all the help and support so far.

Geoff.

On Sun, 6 Jun 2010 14:21:16 -0700 (PDT), Keith Dysart
<keith.dysart@gmail.com> wrote:

>The 100W forward and 50W reflected have no relation to actual powers

From HP Journal V.7n.2:

If an incident wave is applied at
the left as shown in the diagram, the
wave passes down the main arm. In
the region where the lines are cou
pled, a wave 20 db below the inci
dent wave will be coupled to the
"Forward" terminal, while a second
wave 20 db below the incident wave
will be coupled to the resistive ter
mination in the "Reverse" arm.
Since the combined power in the
two split-off waves amounts to only
2% of the power in the main wave,
the main wave is essentially unalt
ered and continues to the right-hand
terminal.
A wave applied at the right end
of the coupler is coupled in an analo
gous manner. Waves 20 db below the
left-traveling wave will be coupled
to the "Reverse" terminal and to the
resistive termination in the "For
ward" arm, while the main part of
the wave continues to the left-hand
terminal.
The couplers thus provide equal
fractions of right-traveling and left traveling
waves at separate termin
als. The ratio of these waves will be
equal to p *, the magnitude of the
reflection coefficient of any device
connected to the output of the cou
pler. This ratio can be measured
(Fig. 4) by applying the outputs of
the "Forward" and "Reverse" ter
minals to the -hp- 416A Ratio Meter,
using suitable detectors to demodu
late the amplitude-modulated power

which must be used with the system. In an ideal directional coupler, no power from a forward wave would be received at the reverse terminal and no power from a reverse wave would be received at the forward ter minal. In practice some undesired power is received at these terminals, although it has been possible to de sign the couplers so that this unde sired power is at least 46 db below the parent wave, i.e, at least 26 db below the desired wave at the oppo site terminal. In other words the di rectivity of the couplers is at least 26 db (30 db in the lower frequency couplers) over the complete fre quency range [Fig. 3(a), (b)]. The coupling mechanism itself consists of quarter-wavelength sec tions of the conductors placed suit ably near one another to achieve the desired degree of coupling. The combined effects of electrical and magnetic coupling impart directiv ity to the coupled wave. The unused terminal of each of the auxiliary arms is terminated in a special widerange low-reflection resistor to ab sorb any power coupled to that ter minal.

Again Wim, we're not on the same page, so let me quote from your
eariler post:

"Virtually all high efficient amplifiers work in voltage saturated
mode
and are therefore not operated at maximum available power, therefore
their output impedance doens't match the expected load."

I have not been talking about MAXIMUM available power, only the power
available with some reasonable value of grid drive. In the real world
of amateur radio operations, of which I'm talking, when we adjust the
pi-network for that given drive level, we adjust for delivering all

the AVAILABLE power at that drive level. When all the available power is thus delivered, the output source resistance equals the load resistance by definition. We're now not talking about changing the load, phase or SWR--we're talking about the single condition arrived at after the loading adjustments have been made.

And Tom, why would the source be reactive when the pi-network is tuned to resonance? And because the source resistance of the (tube) power amp is non-dissipative, its reflection coefficient is 1.0 by definition, and so it cannot absorb any reflected energy, and therefore re-reflects it.

Walter was the first to place things in a book and a book is the first
point of reference in this newsgroup
Nothing personal Richard, but it is obvious that engineers are totally

split as to what theorem is correct and the one to be used. There is no way
you will get agreement if they all insist their position is correct and thus other positions are not worth consideration.You may be correct in your position but the idea of change is not in your favor.

I don't think you can use them. Those connectors won't fit RG-6a/u
QS. Different outer diameter and center conductor diameter. The
RG-59 is slightly smaller than the RG-6QS. The RG-6a/u QS will most
likely not even fit into the connector.

Note the difference:
<http://www.firefold.com/RG6U-Male-F-Compression-Connector-PPC-P2291C1145.aspx>
<http://www.firefold.com/RG59U-Male-F-Compression-Connector-P1966C1145.aspx>

Like I ranted, you should have gotten F connector and used adapters
such as this:
<http://www.firefold.com/BNC-Male-to-Female-F-Type-Adapter-P2782C1145.aspx>

The compression tool seems tolerable. However, I've had some
experience with the stripping tool. They work, but the blade
cartridge wears out rather quickly. My guess is about 30 connectors
and it's gone. I use a thermal wire stripper at home and in the
office, and my pocket knife in the field.

There are tools and connectors on eBay for RG-6:
<http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=130343999448>

I like Thomas and Betts Snap-n-Seal connectors:
<http://www-public.tnb.com/ps/endeca/index.cgi?a=nav&Ne=3951&N=3949+950+4294951388&Ntt=&more=1&nk=3951>
<http://tnblnx3.tnb.com/emAlbum/albums//070%20Connectors%20USA/SNS%20Wall%20Chart%20Final%202009.pdf>
<http://www.tnb.com/contractor/docs/snapnseal.pdf>
Note that there are different connectors for RG6, RG6 QS, RG59 and
RG59 QS.

From HP Journal V.3n7-8

DIRECTIONAL couplers have been used
widely in wave guide applications for
such purposes as monitoring power, meas
uring reflections, mixing, and for isolation
of signal sources. All of these applications
make use of the property that power flowing
in one direction in the main branch of the
coupler induces a power flow in only one
direction in the auxiliary circuit.

<keith.dysart@gmail.com> wrote:

>The 100W forward and 50W reflected have no relation to actual powers

From HP Journal V.6n.1-2:

Power from the source flows down
the main arms of the two couplers
(Fig. 2) and impinges on the load.
The power split off by the 20 db
forward coupler is all passed to the
forward detector, since the directiv
ity characteristic of the multi-hole
directional couplers prevents any
but a negligible amount of the splitoff
power from turning back and
being absorbed in the coupler's in
ternal termination. The power split
off the incident wave by the 10 db
reverse coupler, however, is essen
tially all absorbed in that coupler's
internal termination because of the
reversed direction of connection of
that coupler (Fig. 2).
If the magnitude of the reflection
coefficient ~.T. of the load is, say, 0.1,
Ã□f of the incident voltage will be
reflected back toward the source. As
this reflection passes back through
the main arm of the reverse coupler,
a 10 db split occurs and is applied
to the reverse detector. The remain
der of the reflection will proceed
back toward the generator where it
will be absorbed in the generator
impedance and in the termination
in the forward coupler.

****

Of course, in regard to this last sentence, HP engineers didn't know
jack-shit about power reflections, especially what could be absorbed
by the source.

These are known generically as "compression connectors", and I recommended the BNC type earlier, because when used with either a BNC-F on the antenna, or a BNC/N adapter to an N-F they are waterproof, and neither depends critically on the retaining nut torque for good electrical connection (as do UHF, SMA and F connectors). Compression connectors do not use a normal hex crimp tool, but a tool unique to themselves, and in the rest of the world, the tools are pretty inexpensive (<US20).

Whilst I say they are waterproof, with force, it is possible to break the front of the connector out of the connector body in the types that I have tested.

If you use ordinary (ie non waterproof) crimp BNCs, you need to figure some way to waterproof the cable jacket to the connector body. Most do not lend themselves to glue lined heatshrink for this purpose. Of course, you could always treat them like UHF series, and wrap the entire joint.

Source record: 9213

I have just read an article regarding an AR Op using a carbon fibre fishing rod to make a 12 foot mobile antenna for mobiling.

My question is, does carbon fibre absorb RF?

The operator has wound 5.2 metres (approx 17 feet) of insulated house wiring in a helical fashion around the rod. He uses an SG-237 tuner as well.

If indeed that carbon fibre is conductive, and he claims he is getting outstanding results whilst operating stationery mobile, then what is happening?

I would appreciate comments.

Sine wave is an ideal wave. The motion to and fro are simmetrical.
In reality no such. The wave source push the medium strongly but it come
back with the lower intensity.
For this reason the wave flow transmits the energy from the source to
distant places.
In fluids take place also the mass flow.

BNC's are still 50 or 75 Ohm. Old versions had different diameter
centre pins in order to acheive the correct characteristic impedance.

If you plugged a 50 Ohm plug into a 75 Ohm socket the larger centre
pin would splay out the female centre connector, so when you plugged a
75 Ohm back in again it wouldn't make contact. It used to be fairly
common practice to paint the body of the connector purple or green in
order to quickly identify the type and so prevent damage.

For the past 20 or so years most manufacturers have used the same
sized centre pin, but the 50 Ohm version has a PTFE skirt in order to
provide the correct charateristic impedance. So they are now
mechanically interchangeable.

Walt, this restriction was not given in the original posting, it is added by you and you exclude many other practical amplifier solutions (like push pull 3...30 MHz no-tune amplifiers, fixed tuned single band amplifiers, emerging high efficiency designs for constant envelope modulation schemes and/or AM with supply voltage modulation).

I fully agree with your statement on optimum matching given certain drive and output impedance in case of (pi-filter) matching, no doubt about this. However there are more flavors as I tried to explain.

Even during SSB modulation with an optimally tuned amplifier without power supply modulation, the amplifier is most of the time operated into current saturation mode (instead of optimally tuned output, given a certain drive). For tetrode/pentode, assuming no voltage saturation, the RF plate impedance is seldom equal to the conjugated load impedance (load impedance will be lower). I think for a triode in common grid operation, this will apply also because of the cathode is not grounded for AC, hence plate impedance increases. I have to be careful now to avoid that I have to do a lot of work to fulfill Richard's requests. I dismantled my PL519 common grid amplifier (<22 years ago), so a cannot measure it anymore.

All amateurs that do not have a tuner inside their PA, have to live with non-optimum VSWR (hence amplifier not operating at optimal tuning, even under CW) or have to insert a tuner. For the latter case, the problem now reduces to a cable and tuner loss problem, as after successful tuning, there will be now power reflected to the PA, hence the PA's output impedance doesn't matter.

Maybe the JC could provide some background behind his question.

Can you (or anyone !) provide some evidence of this, in terms of actual measurements or manufacturers' specifications showing a difference in the "Old" versions ? You are also confusing the effects of conductor diameter versus mating surface diameter. 75R and 50R STILL have different inner conductor diameters to achieve correct Zo; it's the MATING SURFACES which are the same.

I (professionally) used many thousands of BNCs during the timescale you mention. While it IS true that some 75R sockets could be damaged, in EVERY case it was due to the inner conductor of the plug being off-centre. 75R sockets were/are inherently rather fragile.
The problem was caused by a mechanical design weakness in some brands of plugs (I don't remember which manufacturers).
AFAIR, the BBC used 50R plugs/sockets in some 75R video equipment, simply because the 50R socket was more robust, by design.

I have lots of old stock and recovered BNCs dating back at least 20 years. All the 50R and 75R components mate without problem.

Well I've got some old 75 Ohm female to female adaptors in front of
me, marked RS part number 455-933 (but the type associated with the
part number has changed many times over the years). I also have one
marked G37534 which looks fairly similar. Most have been opened up
because they have had a 50 Ohm shoved into them.

However on the one pristine 75 Ohm adaptor I could find, the outer
part of the 75 Ohm centre receptacle is so narrow it would easily fit

the inside of a 50 Ohm centre receptacle.

Unfortunately I can’t find any old Greenpar (or similar) mechanical drawings on the web only the newer types.

Looks like they were prior to IEC 169-8 (1978) which defined
mechanical interchangeability.

I downloaded the mechanical drawings from the Amphenol web pile and
found that the center pin diameter is missing from the drawings. I'll
look elsewhere when I have time.
<http://www.amphenolconnex.com/products/bnc.asp>

I have a box full of 75 coax patch cables I salvaged from a radio
station cleanup. They all mate fine with a 50 ohm BNC jack. The only
difference is that the 75 ohm plug has no dielectric, while the 50 ohm
jack does.

http://www.wbdg.org/ccb/FEDMIL/prf39012_16h.pdf is the MIL drawing for
the plug.
note they only have ONE drawing for the center contact.

They also call out MIL-STD-348 for the pin contact interface.
http://www.dscc.dla.mil/Programs/MilSpec/listdocs.asp?BasicDoc=MIL-STD-348
http://www.dscc.dla.mil/Downloads/MilSpec/Docs/MIL-STD-348/idstd348.pdf
is probably the one you want.

on the plug/pin, dimension C (the ID of the insulation inside the outer
conductor) has a minimum, but no maximum.

Likewise on the socket, dimension E, which mates with dimension C on the
plug does have a maximum, but no minimum, implying you can have a "no
dielectric" version.

Dimension D on the plug (the pin diameter) has only one value 0.052 to
0.054 inches.

Dim M on the socket (OD of center conductor) is 0.081 to 0.089,
presumably to correspond roughly with dimension R on the plug, which is
the same.

If you allow that the thing driving the pi network has an effective source impedance different from the load that the pi network presents to it, then clearly the output impedance seen at the other end (the "50 ohm" end) of the pi network won't be 50 ohms. Try it with some numbers; for example, assume a pi network that transforms your 50 ohm load to a 4k ohm load to the amplifier output, and assume an amplifier output stage that looks like a 20k ohm source. Design the pi network for a loaded Q of 10. I believe you'll find that the source impedance seen by the 50 ohm load is about 11+j18 ohms.

As Wim has pointed out, requiring an amplifier to be loaded and driven in a very particular way unnecessarily dismisses some very important classes of amplifier. What do you do, for example, with a linear amplifier? What do you do with an amplifier that drives a voltage very hard (and for which a simple pi network is inappropriate for matching to a load)? Perhaps an even more basic question is: why exactly do we tune a pi network to present a particular load to an RF amplifier stage? Why should we operate a 6146 with, say, a 3000 ohm plate load? Why not 1000, or 6000?

And what if I set up a tube and pi network for operation such that the apparent output source impedance is 50 ohms (while driving a 50 ohm load), and then I add feedback to the amplifier in such a way that the operating conditions are not changed, but the impedance looking back into the plate is changed?

How did we get to the source resistance of "the (tube) power amp" being non-dissipative? I know there are some of us who don't buy into that...

Cheers,
Tom

Source record: 9225

Hello Walt,

I did some simulations with EL34.

Conditions:
Common Grid circuit, Valve connected as triode, 3.6 MHz.
Vsupply, 600V, Vgrid -58V, bias current 40mA (yes I know that it will run very hot).

Maximum available input power: 9.2W out of 600 Ohms, sinusoidal.

Anode loaded with 20uH, 96pF, 3800 Ohms (parallel circuit), QL= 8.4, so the anode voltage has sinusoidal shape.

Without changing the drive (9.2W), 3800 Ohms with 96pF gives highest output power of 64W (Vanode = 698Vp). So power gain is 7.0.

Output impedance:
Change to 4100 Ohms load gives Zout = 1826 (voltage saturation),
Change to 3500 Ohms load gives Zout = 4350 (current saturation),
So for small change in Zload, Zout will be close the load resistor that gives maximum power. This supports that under well-matched conditions, given a certain drive level, Zout = ZLoad.

Input power reduced with 3 dB, output becomes 32.6W (Vanode = 497.5Vp, gain = 7.08). There is a slight increase in gain showing that at 64W the amplifier is not into deep voltage saturation.

Output impedance at 32.6W output:
Change from 3800 to 3500 Ohms gives Zout = 8100 Ohms.
This shows that reducing the drive level (without changing the matching) results in Zout not equal to Zload for this triode common grid circuit.

Also shown that small changes in load (reduction or increase seen at the anode) results in changes in output impedance. That is why I used three resistance values for determining Zout at well-matched output.
I used low frequency to avoid endless matching because of parasitic capacitances and I also skipped the output matching (I have to work sometimes, so time is limited).

It is not strange to see an RF swing above supply voltage as this is a common grid circuit with cathode grounded for DC.

If you like, I could do same exercise for modern amplifier topologies, but be prepared to see unexpected results (As Tom, K7ITM already noted).

Best regards,

Wim

Can you give measured data for the losses? (or reasonably high fidelity
model data). I don't think the losses are *big* in either case, so you
might be looking at the difference between 5% loss and 7% loss, which is
negligible in the overall scheme of things.

I'd be willing to bet a six pack of frosty cold beverages (not the
antenna) that it's not a 75% loss vs 10% loss situation..

Maximum current will be at the tuner which is not desirable.

yes and no. I don't think, on a short antenna (2 meters long, here, but
let's say up to 3 meters) the difference will be significant;especially
when viewed in the context that the whip is next to a big giant metallic
object. They're ALL short compared to a wavelength, so the difference
in ideal gain is going to be somewhere between 1.64dBi (infinitely short
dipole) and 2.15dBi (half wavelength dipole)... And, given it's a
(mostly) vertical antenna, for which you have no real control over the
propagation path, who's to say that the fatter lobe on the infinitely
short dipole might not be better than the slightly skinnier one on the
half wavelength one.

(yes, it's a monopole..same idea though)

> The location of the loading coil has a large effect on the current

Quantify "large"...

Is it bigger than 3 dB? (100%)
Bigger than 1 dB? (25%)

You're already taking a 5-6 dB hit just by having it bolted to a car
driving down the road. While I wouldn't say you should capriciously
throw away performance, you're already in a compromise situation.
Having less wind drag or a broader operating band might be a bigger
advantage than a dB or two.

Where you have it is about the worst

> My mobile antenna is center loaded in the driving config.

And what's your operating bandwidth? Can you tune anywhere in the 40m
or 80m band? What's the efficiency of your system when you're not right
at the "sweet spot"...

The efficiency of the autotuner system is pretty constant across the band.

Now, it's possible all one needs to do is check into the nets at fixed
frequencies within a few kHz.. In which case the fixed tune system works
fine (assuming you've tuned it while actually driving...)

If you operate "mobile" (as opposed to portable, parked by the side of
the road), the autotuner takes care of the substantial change in antenna
impedance as the wind pushes it back. Or, one could mount it in the
center of the roof and guy it.. (been there, done that)

that's a pretty big difference.. (12 dB implies a factor of 16.. that's like most of the Tx power being dissipated somewhere, and that sounds like "component melting" levels)

Have you a link to the data and test methodology?

On Jun 6, 4:58 pm, Roy Lewallen <w...@eznec.com> wrote:
> This is why, for
> example, a center loading coil must have more inductance than a base
> loading coil to effect the same change in reactance at the base.

The following is based on a fixed length antenna.

The phase shift at the top of each coil is associated with the abrupt shift in characteristic impedances at the coil-stinger junction (according to W8JI). When a base section is added to a base-loaded antenna, there is an opposite abrupt shift in characteristic impedance at the base-coil junction. That bottom (negative) phase shift subtracts from the (positive) phase shift at the coil-stinger junction so more phase shift must be added through the coil to compensate for the phase shift lost at the base-coil junction. Increasing the coil length provides the necessary additional phase shift.

Assume a loading coil has a characteristic impedance of 4000 ohms and the stinger has a characteristic impedance of 600 ohms at the coil-stinger junction. Given the impedance looking into the stinger, it is easy to calculate the phase shift at the coil-stinger junction. Let's (for instance) say the stinger's input impedance is 0.25 - j2500 ohms. If we normalize that impedance to the assumed Z0=600 ohms of the stinger, we get very close to -j4.167. The impedance at the very top of the coil is the same and if we normalize to the assumed Z0=4000 ohms of the coil, we get -j0.625 ohms. If we subtract the arctangent of those two values, we get the phase shift: 76.5 - 32 degrees = 44.5 degrees at the top of the loading coil. We can also read that same value from a Smith Chart.

When we go to a center-loaded coil, the calculations are complicated by the resistive portion of the impedance, but we will find a negative phase shift at the bottom of the coil that subtracts from the positive phase shift at the top of the coil. Since we have reduced the total system phase shift by moving the coil to the center of the antenna, we need to add more length to the coil to increase the phase shift through the coil in order to compensate for the negative phase shift lost at the bottom of the coil.

One can emulate the loading coil problem using pieces of transmission line with different Z0s. The basics of shortened dual-Z0 stubs are covered here:

http://www.w5dxp.com/shrtstub.htm

For instance, the following shortened stub has a resonant frequency at which it is electrically 1/4WL long even though it is only 1/8WL long physically because of the 45 degree phase shift between the two sections.

-----22.5 deg 300 ohm-----+-----22.5 deg 50 ohms-----

What happens to the resonant frequency if we move half of the 50 ohm line to the bottom?

----11.25 deg 50 ohm---+---22.5 deg 300 ohm---+---11.25 deg 50 ohm

How many degrees do we need to add to the 300 ohm line to achieve the same resonant frequency as before?
Can anyone out there solve this problem?

David, you are preaching to the choir. I explained before that there is NO interaction between forward and reflected waves because they are traveling in different directions. The only time that coherent, collimated waves can interact is when they are traveling in the same direction in a transmission line.

Keith's argument requires that forward waves and reflected waves interact. I say they cannot interact in a constant Z0 environment. You say they cannot interact. We are on the same side of this argument.

The mechanism of the interaction of two coherent, collimated waves traveling in the same direction is that the superposition process is irreversible. The source photons and the reflected photons are indistinguishable.

This is the standard rebuff with "the rest of the world works
differently" distractions to Walt having stated a premise, described
initial conditions, taken measurements, and having shown the data
supports his hypothesis. The hypothesis is dismissed through shifting
initial conditions to suit an avoidance of committing an honest answer
to Walt's specific and very explicit observation.

Walt, if this community were pressed for an "up or down" vote:

"Does Walt's data support the evidence of a Conjugate Match?"

then you would be out in the weeds with your only supporting vote from
me (and maybe from others who would do this by email).

I doubt this will set off a stampede to the ballot box, but what few
votes are stuffed in, I bet they will have the "up or down" stapled to
a dissertation of "however...."

To this last, if I sinned in that regard, I used only Walt's data, his
equipment references, and his citation sources. As no one else seems
to tread that narrow path, much less commit beyond grandiose
statements, I don't feet too bad.

In the admittedly very few looks I've had at mobile "shootout" results, there seems to be more of a correlation between vehicle size and field strength than antenna and field strength. This comes as no surprise, since the vehicle is usually a comparable or even greater part of the radiating system than the titular antenna, and its coupling to ground has a large impact on the efficiency.

For all intents and purposes, 50 and 75 ohm BNCs (both male and female)
are interchangeable. They have essentially the same dimensions. You
might just see that the 50 ohm male has a rather stubby point, whereas
the 75 ohm version has a somewhat more steadily-tapered pin - but,
unlike N-connectors, the 50 ohm male certainly doesn't cause damage to a
75 ohm female.

The thing which mainly causes the impedances to differ is the amount of
PTFE dielectric present, in both sexes. On the 75 ohm version, you will
normally see that it has been reduced considerably compared with the 50
ohm. Even with less dielectric, the 75 ohm version is still a bit
unhappy with having too much, and this tends to lower the impedance to
somewhat less than 75 ohms.

However, for all intents and purposes, you probably won't notice any
significant difference between 50 and 75 ohm BNCs (mixed or not).

> Have you a link to the data and test methodology?

I summarized the data from three CA 75m mobile shootouts at:

http://www.w5dxp.com/shootout.htm

I don't recall a test methodology being published. The test receiver consisted of a ferrite loop antenna in the far field feeding a lab-grade RF voltmeter. The power incident upon the 75m mobile antenna system was assumed to be forward power minus reflected power on the coax to the antenna system, measured using two Birds. The receive results were normalized accordingly. I may have left out a detail or two.

The SG-230 plus 11.5 whip at -12 dB was equal to a 75m hamstick. I entered both the top-rated (0 dB reference) antenna and the (-12 dB) autotuner+whip on the same vehicle. When I "superposed" all of the three results, I assumed 0 dB for each top-rated antenna and let the rest fall where they might. That may or may not have been a reasonable assumption.

I suspect the SG-230 is designed to dissipate 100 watts (using large #2 material powdered-iron toroids). During one shootout episode, I forgot to attach the antenna to the mobile mount. The SG-230 faithfully tuned to close to a 1:1 match on the input - with a near-infinite SWR on the output. It was a damp foggy day and the mobile mount arced. That taught me not to mount the SG-230 unobserved in the attic. :-)

Hello Richard,

I think, most people that are willing to read will support Walt's
statements on output impedance of an amplifier under matched output
power (given a certain drive condition). However there are many
practical circumstances where Walt's conditions are not met.

As soon as you change the drive (for example during an AM or SSB
transmission), your matching is no longer guaranteed, especially when
using circuits with current behavior (tetrode/pentode, common grid,
etc). See my EL34 posting. Note that under practical circumstances,
this is no problem.

As soon as you change the load (without changing the matching), you may run into current or voltage saturation, of course depending on phase of VSWR. As you know many people use non-tune solid-state amplifiers, so they don't have the possibility to tune/match for maximum output given certain drive. That means, live with it, or use an external tuner where you don't tune for maximum power, but for minimum VSWR presented to the PA.

Amplifiers for constant envelope modulation use saturation to increase efficiency (and accept the loss in gain). These are deliberately used under mismatch, therefore the gain is less with respect to a non-saturating approach. You can also see this from the Pout versus Pin curve for FM transistors. I know that severak CB owners retuned (or even modified) the output stage to get 1 dB more power, but they did forget that the final transistor had dissipate 2dB more. Result: some japanese transistors became very popular (2SC1306, 1307, 1969, etc).

High efficiency circuits are the extreme case and are entering the amateur world. Active devices behave like switches, output impedance can have every value as long as it is close to the edge of the passive Smith Chart. Amplitude modulation with these topologies can only be done via supply voltage modulation. Tuning for maximum power with an external tuner will surely destroy the amplifier if no protection is present.

For me it was a surprise how this thread developed.

Best regards,

Wim

> VK2KC

I can tell you my experience with an about 7.5-meter carbon-fibre fishing rod, that I was intending to use as support for a 10-MHz vertical (the rod was secured to an insulated support, with some radials lying on the ground).

What is did is to run a bare copper wire along the rod, fixing it to the rod every 30cm or so using scotch tape. So, the antenna was the wire, and the rod was just a support.

After tuning the wire for perfect resonance at 10.1 MHz, I applied 1kW RF power to the antenna. The result was that the rod (and the tape) got quickly burned at most of the points where the wire was fixed to the rod (the high-voltage points).

It can be easily concluded that:

- the carbon-fire rod is indeed conductive
- its resistance is however too high for plainly using it as a radiator (i.e.without the copper wire)
- even though running low power one would probably not experience the problems I had, the antenna loss (in dB) caused to the fairly high rod resistivity would anyway be significant, independently of whether one runs low or high power.

Time to sum up where we are in this cause cï¿œlï¿œbre, I think.

The diameter of the centre pin in current production BNC plugs is specified as between 1.32 and 1.37mm (0.052 and 0.054 inches). This is the same for 75R connectors which are detailed in MIL-STD-348B (9Feb 2009), and 50R connectors, shown in MIL-STD-348 (20 April 1988). The earlier document does not refer to the Zo, but the drawing is clearly of a 50R socket with the extended dielectric surrounding the split pin.

Therefore - all compliant BNC connectors are mechanically compatible between 50R and 75R from April 1988 onwards. There are NO mating damage problems for current production items.

It has been suggested that prior to the introduction of IEC 169-8 in 1978, which defined interchangeability, there may have been differences in the pin diameters between 50R and 75R plugs. This will only be resolved by the actual measurement of plugs known to have been manufactured prior to 1978 - or someone producing specification documents from the time.

The definitive specification of BNC connectors would appear to be contained within IEC standard document 169-8. This does not seem to be easily available - copies must be purchased at considerable expense from the IEC. Has anyone got access to a copy of this document ?

I haven't followed this thread since it's been beaten to death so many times here before. But there's an interesting fact that might have been overlooked, and might (or might not) be relevant:

If you put a directional coupler such as a Bruene circuit at the output of a transmitter, and use its "forward" output to control the transmitter power to keep the "forward" directional coupler output constant, you'll find that the power output vs load resistance characteristic is exactly the same as if the transmitter had 50 ohm output impedance. This is assuming that the directional coupler is designed for a 50 ohm system, and that the load is purely resistive. It also assumes that any load is left in place long enough for the feedback circuit to stabilize. The effective source impedance to a very rapidly varying load (that is, one changing so fast that the ALC feedback system doesn't have time to respond) would be the open-loop output impedance which could be quite different. I haven't taken the time to analyze how it behaves with a complex load.

I stumbled across this some time ago when designing a rig using this ALC method and found it interesting. I believe many if not most modern solid-state transmitters use this ALC method.

I'm told that composite carbon materials have quite different conductivities in different directions, like a laminated transformer core. At least this should minimize eddy currents.

N connectors don't have any dielectric in the mating region, so the pin diameter would have to be made smaller for a 75 ohm impedance. Maybe N connector incompatibility issues have morphed into misconceptions about BNCs. I don't think I have any 75 ohm N connectors (assuming such things exist) to look at.

Roy Lewallen, W7EL

That certainly explains why the diameter of the 75 ohm N pin is much,
much less than the 50 ohm. The two are certainly not mateable.

I must admit that, in the back of my mind, I'd occasionally wondered why
- and now, after over 46 years of successfully not getting them mixed up
too often (at work, it was a hanging offence to put a 50 ohm male in a
75 ohm female), all is clear! I don't know why it never dawned on me.
I'm fully familiar with the difference between the BNCs.

It looks like the rod I have used was built by winding a narrow tape on a
tapered cylindrical support (in spiral fashion).

>physicists, have not been forced to follow the energy flow.

There is no interaction between the waves, they may be superimposed,
and maybe their photons are indistinguishable, but there is no
'interaction'. interaction implies that one wave affects the other,
energy is transferred or fields are affected, such things occur in non-
linear media, but not in linear ones.

Hello Tom,

Well, the reason I chose to discuss only the tube amp with a pi-network filter and impedance transformer is that that arrangement is the only one I've measured, and that I'm not sufficiently acquainted with other arrangements to discuss them.

As to your question, why not use plate loads of 3000, 6000 or 1000? Because the transceivers I measured using two 6146s in parallel are Kenwood TS-830S and Heathkit HW-100. I don't remember the exact plate load with the HW-100, close to 1400 ohms, while the TS-830S was 1400 ohms. I had no control over those plate loads because the plate and grid voltages were preset, and 1400 ohms is the RL I measured at the input of the pi-network when the grid drive and the network were adjusted to deliver precisely 100w to the load 50-ohm load.

Now concerning the non-dissipative source resistance of the tube-type power amp. There are two separate resistances in the amp, the cathode-to-plate resistance, Rpd, that accounts for all the dissipation in the tube; and the output-source resistance that is non-dissipative. It is a common myth that an RF power amp cannot have an efficiency greater than 50% when conjugate matched to the load, because half the RF power is dissipated in the source resistance. This is not true, because when the amp is operating properly, resistance Rpd is less than the output source resistance, thus allowing more power delivered to the load than that dissipated in the plate-to-cathode resistance. The output source resistance is derived from the voltage-current ratio E/I that appears at the output terminals of the pi-network. A ratio, as such, cannot dissipate energy, but the load it feeds does.

Using an example from Terman's Radio Engineer's Handbook I explain this phenomenon in great detail in Chapter 19 in Reflections, and further in Chapter 19A, an addition to Chapter 19. Both are available on my web page at www.w2du.com. Chapter 19 appears in 'Read Chapters from Reflections 2', and 19A appears in 'Preview Chapter from Reflections 3'. The entire Chapter 19 appears in Reflections 3, which is now available from CQ. I invite you to review these Chapters.

that seems quite plausible. A bigger vehicle essentially means a
physically larger antenna (think of the whole system as a dipole fed off
center, and a fan on one side but not the other.

Hello Roy,

If you have sufficient headroom and under the conditions you
mentioned, you mimic a 50 Ohms source. I think it also works for any
(complex) loads (I couldn’t find why not).

The difference between a real 50 Ohms circuit may be that the phase of
the belonging EMF may change, in many amplifiers phase shift is
somewhat excitation dependent, but who bothers?

I expect such scheme in combination with VSWR measurement also, as
several PAs have a reverse power indicator present (the other half of
a the Bruene circuit). You need the reverse power indication to avoid
destroying active devices and/or intermodulation distortion due to
voltage saturation.

Imagine that you have full reflection |RC| = 1 and it appears at your
active device as RC=-1. You want to maintain the original forward
power. Your active device has to deliver in that case double the
current at zero collector/plate voltage to maintain same forward power
as under matched condition. The actual power delivered to the load is

zero (as the active device supplies current, but no voltage, RC=-1 means a short circuit). This will result in massive dissipation in the active device.

In case of RC=+1, it has to provide double the voltage with no current. In other circumstances you will have a significant phase shift between current and voltage resulting also in increased device dissipation and inconvenient combinations of instantaneous voltage and current. So above some value for VSWR, you may have to reduce the forward power

I had a discussion recently about the power control scheme for TETRA terminals, but we couldn't find the answer to what is happening under high VSWR (so we have measure it). It only states VSWR<2.

Best regards,

Are you stating that such a radiator with a physical length of 1/8-lambda has ALL of the electrical characteristics of a self-resonant, 1/4-wave radiator -- including its radiation resistance, radiation pattern, and peak gain in dBi?

Zero reactance at the input terminals of an electrically short radiator does not mean that such a radiator is the electrical equal of every other radiator with zero reactance at its input terminals.

Zero input reactance for short radiators can be attained by various means, but the intrinsic, real radiation resistance/pattern/gain of an antenna is a function of the electrical length, configuration, and installation environment of the conductor(s) exposed to free space, regardless of the reactance at the feedpoint -- whether that reactance is zero or not.

Yes, I was referring to the operating region at which normal power is maintained. As you pointed out, rigs employing this method will only maintain the same "forward" power over some range of SWR beyond which they'll begin reducing it, otherwise they'd self-destruct in the attempt. In the reduced power region, the apparent 50 ohm output impedance of course no longer holds.

Hi Roy,

This application that you describe was written up in exactly the same
terms within the recent HP Journals I have posted extracts here. HP
used Directional Couplers (the Bruene circuit, also called a bridge,
qualifies too but uses a non-wave design) to separate out the forward
from the reverse power reflected from the mismatch to create a
reference power. Later, HP and others strapped the signals back into
the source in much the manner you describe.

The rudimentary version can be found in HP Journal v.6 n.1-2. HP
Journal v.12 n.4 strengthens the concept with hard copy sweeps of the
reflection coefficient of a load. By HP Journal v.16 n.6, we have the
description of automatic level control. For the 45 years beyond that
last article, more refinements.

So, that is one vote for (with bulky provisos), and one vote against
(with bulky provisos) going into the ballot box.

Walt, if this community were pressed for an "up or down" vote:

"Does Walt's data support the evidence of a Conjugate Match?"

It seems writing the phrase "Conjugate Match is shown by Walt's data"
is a fearsome (loathsome) step to take, or can be taken with
qualifiers and other soporifics to deaden the pain.

Walt's data shows evidence of a Conjugate Match.

<keith.dysart@gmail.com> wrote:

>The 100W forward and 50W reflected have no relation to actual powers

From a current NARDA specification:

GENERAL COUPLER OPERATION
A coaxial directional coupler has the general appearance
of a section of coaxial line, with the addition of a second
parallel section of line and with one end terminated (see
Figure 9). These two sections are known as the main and
auxiliary lines. The two lines are internally separated from
each other; the amount of spacing between lines determines
the amount of RF energy that may be transferred
from the main line to the auxiliary line. In operation, assume
that energy is fed into port A of the main line. Most of
this energy will appear at output port B of the main line.
However, a fraction of this energy (determined by coupling
value) will also appear at the coupled port C, of the
auxiliary line.
A dual-directional coaxial coupler, such as the
reflectometer coupler, consists essentially of two single-
ended couplers connected back-to-back. Perhaps
the most important characteristic of the directional coupler
(and the one from which its name originates) is its
directivity.
...
For reflectometry applications,
the dual directional coupler, incorporating two
auxiliary outputs, permits the simultaneous sampling of incident
and reflected power.
...
RF power applied to
the load is reflected to some degree depending on load
characteristics, thereby resulting in a voltage standing
wave ratio (VSWR) which is reflected back to the main line
output port. this reflected power is coupled out of the reflected
output port at a level 10 dB down from the reflected
power level at the load.

My interests lie in understanding the behaviour of transmission lines
to a level necessary to predict their basic behaviour. I did not find
that I needed power flux to achieve this so I have not explored it. I
suspect that you are right and it is an interesting topic.

Sine wave. Square wave. Triangle wave. Sawtooth wave. Waveform.
Waveshape. 'Wave' seems to fit well with many words. I do not see a
problem.

When I was trying to understand the behaviour of reflections in
transmission lines, I found it extremely valuable to consider
waveforms
other than sinusoids. Step functions into open, shorted and properly
terminated lines were quite enlightening. The arithmetic is much
easier to perform than for sine waves and some of the results rather
surprising.

For example, apply a step function from a matched generator to an
open transmission line. After the step makes one round trip, there
will be a constant voltage everywhere on the line and the current
will be zero everywhere. The wave reflection will show that there
is a constant forward wave which is summed with a constant reflected
wave to produce the constant voltage on the line. This is a strong
example of why there is not necessarily power in the forward and
reflected wave.

Other interesting thought experiments are pulses and pulse trains.
Arrange the timing so that a forward pulse collides with a reflected
in the middle of the line. What are the voltages and currents that
would be observed? Try alternating positive and negative pulses.

And lastly, inject signals simultaneously from both ends of a
transmission line. What is the result?

When doing these, I would compute the power provided by the source
and dissipated in the source resistor (I tend towards ideal
Thevenin generators to simplify the analysis, though it is
worth occasionaly doing the same with Norton), the energy stored
in the line and the energy being dissipated in the load resistor,
if there is one. Dealing with all of this in the time domain can
help make the energy flows clear.

These simple thought experiments definitely helped my understanding.
Some of the assertions that have been made can be shown to be false
when tested with these waveforms and analysis.

Your concepts violate the laws of physics so no, I am not going to
discuss it with you until you correct your numerous technical
blunders. You need to give up on waves that violate Maxwell's
equations. You need to give up on the occurrence of reflections where
reflections are impossible. You need to give up on the concept that
photons obey your every whim.

Are you aware that visible light and RF waves are identical phenomena,
just at different frequencies? An RF transmission lines operates much
the same as fiber optics.

> When I clip my instantaneous voltmeter across a line and measure
> 0 for all time, I can confidently say that no energy is flowing, for
> there is not. I am curious as to what you would answer?

I have already answered. I agree with you that there is no NET energy
flowing across that boundary. All it means is that the forward
Poynting vector and reverse Poynting vector are of equal magnitudes.
The reflection coefficient at that zero voltage point is zero so
reflections are impossible. Yet, your concept requires a reflection at
every node - which violates the laws of physics. Until you eliminate
those magical metaphysical functions from your concepts, they are "of
limited utility", to quote Hecht.

Again, you are saying that there is zero traffic on the Golden Gate
Bridge because the northbound vehicles equal the southbound vehicles.
There is zero NET traffic, but such information is worthless. Someone
still has to repair the bridge.

> from another point of view.

Miguel, you might be surprised to know that I got the constructive/
destructive interference concepts first from Walter Maxwell's,
"Reflections". Take a look at "Sec 4.3 Reflection Mechanics of Stub
Matching". Walt says:

"The destructive wave interference between these two complementary
waves at the stub point causes a complete cancellation of energy flow
in the direction toward the generator."

"Conversely, the constructive wave interference produces an energy
maximum in the direction toward the load, resulting from the sum of
the two reflected waves and the source wave."

Walt clearly understands that wave cancellation, interference, and
redistribution of reflected energy back toward the load is involved
with his "conjugate mirror" and virtual-short-circuit concepts.

So you see the concept of wave cancellation of complimentary reflected
waves at a Z0-match didn't come first from me. The concept of all of
that energy involved in wave cancellation changing direction and
joining the forward wave didn't come first from me. I only resorted to
the field of optics to gain additional technical information and
expanded on Walt's original "Reflections" concepts in my article.

> linear media, but not in linear ones.

Note that I was not talking about forward and reflected waves in a constant Z0 transmission line. I am talking about the four wavefront components that are generated at an impedance discontinuity. It has been proven in experimentally that those waves indeed interact. In fact, the transfer of destructive interference energy from wave cancellation to the areas that permit constructive interference is obviously interaction since the canceled waves disappear in their original direction of travel. But, as the FSU web page says, they are not annihilated - their energy components simply change direction.

How can you possibly argue that wave cancellation doesn't require wave interaction? Those two waves completely disappear in the direction of destructive interference. Dr. Best argued that those two waves don't interact and continue propagating (completely devoid of energy) forever in the direction of original travel. I asked him to prove that his phantom waves exist but he could not. Is there such a proof available?

At a 1/4WL thin-film coating on non-reflective glass, when the internal reflected wave arrives with equal magnitude and 180 degrees out of phase with the external reflection, wave cancellation occurs. That is an *obvious* effect that one wave has on the other. Wave cancellation is an obvious interaction. In the s-parameter equation:

b1 = s11*a1 + s12*a2 = 0

the s11*a1 wavefront has obviously interacted with the s12*a2 wavefront to accomplish wave cancellation.

Hi John

As I remember too if you use plastic conduit (in VK) the orange stuff has no carbon but the grey stuff does. ie it has carbon mixed in when it is extruded.

I don't know how good that info is, it's comes from way back in anecdotal land. I just assume grey stuff is not to be used for radio antenna system!

Not directly on topic but may be related.

I have heard the same thing, but have used the grey conduit for antenna
construction in the past. I noted that a 2mtr band slim jim (J pole variant)
antenna had the same low SWR with and with out being inside a length of 32mm
grey conduit. I would assume some affect on the SWR if there was any
interaction.

<keith.dysart@gmail.com> wrote:

>The 100W forward and 50W reflected have no relation to actual powers

From MECA, makers of Isolators - their application:

The isolator is placed in the measurement path of a test bench between a signal source and the device under test (DUT) so that any reflections caused by any mismatches will end up at the termination of the isolator and not back into the signal source. This example also clearly illustrates the need to be certain that the termination at the isolated port is sufficient to handle 100% of the reflected power should the DUT be disconnected while the signal source is at full power. If the termination is damaged due to excessive power levels, the reflected signals will be directed back to the receiver because of the circular signal flow.
...
MECA offers twenty-four models of isolators and circulators in both N and SMA-female connectors with average power ratings from 2 - 250 watts.

Some values:
9 +/-1 Ohm (real impedance), reference impedance 16 Ohms, 8 MHz
amplifier (ISM). Exact value requried because of additional filtering,
based on several IRF110, push pull.

<2 Ohms (small reactance present), 10V/1A driver (sinusoidal), 700
kHz, slightly saturating class C output stage based on single mosfet.
RF feedback present to guarantee value below 2 Ohms. also here,
certain maximum value was required for the application

|RC| > 0.80 (actual value depending on type of additional filtering in
between), >5kW pulsed power amplfiier, non 50 Ohm application.

Actual value not important, but is a recent project, so I knew from
memory.

See also EL34 example in posting to Walt.

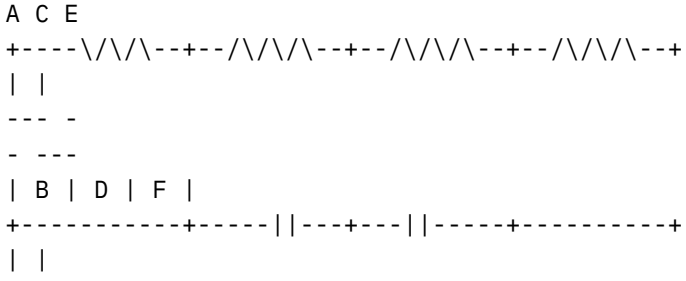
Here is a thought experiment for you.



Four resistors, equal value.
Four DC sources, equal value.
Voltage A-B = 0, no power past here.
Voltage C-D = 0, no power past here.
Voltage E-F = 0, no power past here.

No power crossing the boundaries on either side of the resistor between
A and C. The resistor is not directly connected to a supply, how is it
dissipating power, if any?

(Yes, I do know the answer.)

Good day Richard,

You have located several examples from reputable vendors where the
behaviour of directional couplers is described in terms of power
in a forward and reflected wave. This model of behaviour works within
its limits and allows for convenient computation and prediction of
the behaviour. But all of these papers have the appropriate
discipline and do not ask the question "where does the reflected
energy go?" which is good, for this exceeds the limits of the
model.

As soon as one assigns tangible energy to the reflected wave, it
becomes reasonable to ask for an accounting of this energy and
the model is incapable of properly accounting for the energy.

Following this weakness back through the model, the root cause
is the attempt to assign tangible energy to the reflected wave.
Think of it as a reflected voltage or current wave and all will
be well, but assign power to it and eventually incorrect
conclusions will be drawn.

For those who understand this, and know that "where did the
reflected energy go?" is an invalid question, using the power

model within its limits will not cause difficulties. But for those who are not careful, great difficulties arise and a lot of fancy dancing is offered to work around the difficulties, unsuccessfully.

Just for fun, here is a simple example.

100V DC source, connected to a 50 ohm source resistor, connected to 50 ohm transmission line, connected to a 50 ohm load resistor. Turn on the source. A voltage step propagates down the line to the load. The impedances are matched, so there are no reflections. The source provides 100W. 100W is dissipated in the source resistor. 100W is dissipated in the load resistor. Energy moves along the transmission line from the source to the load at the rate of 50W.
All is well.

Disconnect the load. A voltage step propagates back along the line from the load to the source. In front of this step current continues to flow. Behind the step, the current is 0. When the step reaches the source there is no longer any current flowing. The source is no longer providing energy, the source resistor is dissipating nothing, and neither is the load resistor.

Proponensts of the power model claim that energy is still flowing down the line, being reflected from the open end and flowing back to the source. Since the source is clearly no longer providing energy, great machinations are required to explain why the reflected 'energy' is re-reflected to provide the forward 'energy'.

But really, does anyone believe that a length of transmission line, charged to 100V voltage with zero current flowing, is actually simultaneously transporting energy in both directions?

For even more fun, replace the ideal conductors in the transmission line with some lossy conductors. How much of the reflected and re-reflected energy flowing up and down the line will be dissipated in the conductors? Remember that the current is zero, everywhere along the line.

...Keith

It took a lot of words to say "no, I am not ready."

It is too bad, because the time domain is quite enlightening.

Then one is using the wrong model which is typical of many RF engineers. Optical physicists have been accounting for reflected energy for decades. That one is ignorant of where reflected energy goes is not a good reason to abandon the law of physics that says that *ALL* EM waves contain ExH energy, including reflected EM waves. EM waves cannot exist without ExH energy so you might as well say that reflected waves do not exist at all because that is the logical conclusion based on your false premises.

Optical physicists have been aware of the power-density/interference equation for a long, long time. It is covered in any good reference book on optics, e.g. by Hecht and by Born and Wolf. I have posted the details - why do choose to remain ignorant? At least take time to comprehend the technical information available from the field of optics and report back to us why many decades of that EM wave knowledge is wrong. Here is the equation that explains where the reflected energy goes. All you have to to is track the energy back in time.

Ptot = P1 + P2 + 2*SQRT(P1*P2)*cos(A)

where A is the angle between the two voltages. The last term is known as the "interference term".

When two coherent, collimated, signals interfere while traveling in the same direction in a transmission line: If they are 90 degrees apart, there is zero interference and the I and Q components are easily recovered.

If they are less than 90 degrees apart, the interference is constructive and the phasor superposition of the two waves results in *more power in the total superposed wave* than in the arithmetic sum of the two powers. The extra energy has to come from somewhere. In the absence of a local source, the extra energy has to come from destructive interference in the opposite direction, e.g. at a Z0-match.

If they are between 90 degrees and 180 degrees apart, the interference is destructive and the phasor superposition of the two waves results in *less power in the total superposed wave* than in the arithmetic sum of the two waves. The "left-over" energy has to go somewhere so it

has to be delivered in the opposite direction to the area that supports constructive interference.

Here is what Hecht said: "Briefly then, optical (EM wave) interference corresponds to the interaction of two or more (EM) lightwaves yielding a resultant irradiance (power density) that deviates from the sum of the component irradiances."

Hecht's statement hints to where the reflected energy goes. In the case of wave cancellation at a Z0-match that eliminates ExH reflected energy flowing toward the load, all of the ExH reflected energy is recovered and redistributed back toward the load.

Only if the model is inadequate. Optical physicists assign tangible energy to reflected waves all the time. Many are probably reading these postings and laughing at the collective ignorance about EM waves.

Take a look at this web page:

http://www.teachspin.com/instruments/moderni/experiments.shtml

Scroll down to, "Using Dielectric Beamsplitters to find the "missing energy" in destructive interference". There it is, all spelled out for you - where the reflected energy goes. Reflected energy is never actually missing - what are missing are a few of the brain cells that need to be used to think about reflected energy. :-)

> For those who understand this, and know that "where did the

Yes, throughout history, ignorant people have brought great difficulties upon themselves because they refuse to alleviate their ignorance. Those who refuse to learn from their mistakes are destined to repeat those same mistakes. And you were making these exact same mistakes years ago. You can lead a horse to water ...

In his Nov/Dec 2001 QEX article, Dr. Best attempted to explain where the reflected energy goes. Shackled by ignorance, he got many things wrong e.g. phantom EM waves that exist without energy. But the article alludes to the conceptual path that needs to be taken to alleviate that ignorance. In "Wave Mechanics of Transmission Lines, Part 3", Dr. Best published the above power-density/interference equation although

he ignorantly asserted on this newsgroup that interference did not exist.

Interference resulting from superposition at an impedance discontinuity is the key missing link in explaining everything that happens to the energy in a transmission line including Roy's food-for-thought article. Why is there so much reluctance to adopt a proven law of EM wave physics from the field of optics?

OK, their having stated explicitly that, and having it in black and white from competent authority is just as insufficient as Walt's method and data. Bench experience to this issue makes a lot of armchair theorists uncomfortable.

To your credit, you responded to the witness of evidence. It's like the rest threw you under the bus.

John,

Thank you for the clarification.

Too bad it is no longer available. I think the current W2AU is a true
balun rather than a center insulator. I never used the strap for
lightning protection.

The last balun I owned or used was tossed in the Atlantic Ocean on
1980 and I have never used one since then. I will have to live
with my repaired W9INN center insulator.

>Some values:
>9 +/-1 Ohm (real impedance), reference impedance 16 Ohms, 8 MHz
>amplifier (ISM).

Taking my statement and your response at face value, you are
describing how a source that formerly exhibited 50 Ohms was drawn down
to 9 +/-1 Ohm (real impedance). What "real impedance" is? is not
something that I will dwell on. Instead, I will ask how this shift
was induced. Or perhaps you are using a 16 Ohm system. If so, this
lacks too many details for consideration. When I had Walt's 300+ line
hypothesis, I also had access to his service manual for his equipment,
the final tube specification, and his measurement data. In short, I
am impressed only by data, not results.

Given the "some values" that you offer continues in disjointed
discussion as a sort of short-hand description for a project known
only to you, then these distractions draw this further away from a
conclusion. I also see your directions to wander the threads for
vague side bars of discussion. Supposedly, this is instruction for me
to draw together and connect the important details of your point for
you. No, thank you. Too many in this group contribute teasing
details in their coy writing and none of them have the power to
intrigue me with that.

Your "some values" looks vaguely interesting, but I would suggest you put effort into describing your complete scenario with as much care as Walt's 300+ line posting that laid bare his complete hypothesis. I offered you a specifically new thread that I originated solely for one issue where I see no discussion from you - quid pro quo?

And returning to the matter at hand - Up or Down:

"Does Walt's data support the evidence of a Conjugate Match?"

I cannot see pursuing your inquiry with your own example if you cannot offer a fixed answer here. That would put me in a position of embarking on a ponderous journey where, simultaneously, you and Walt both DID AND DID NOT demonstrate your claims. Paradox is suitable only for Operetta by Gilbert and Sullivan.

Hello Richard,

You asked for what it IS, several times, so you virtually left me no choice.

Especially the first one (Zout = 9 ohms where the load is 16 Ohms, RCout = -0.28) is very well documented as it was designed to have this value. Without the extra measures, the value was below 9 Ohms. The amplifier is time limited fully short circuit proof, so it was not difficult to determine Zout at various loads. I put myself into problems when publishing the documentation over here.

When we go back to my first posting in this thread (the first reply) where I stated that amplifiers do not show 50 Ohms in general, is not that strange and doesn't violate Walt's conclusions.

When I understand it well, Walt assumes tuning for maximum output at a given drive (not necessarily the maximum drive). As mentioned earlier, I support his findings.

When you don't touch the plate and load capacitor and change from 50 Ohms to a load with VSWR = 2, you violate Walt's conditions and the amplifier will no long behave as a 50 Ohms source, hence what happens with the 50W reflected power from JC's posting becomes more complicated then just a transmission line problem.

Walt made a statement in this thread that an amplifier that obeys ZL = Zout can have higher then 50% efficiency. I fully support this statement also (Example Class C amplifier with narrow conduction angle at the edge of current/voltage saturation, with efficiency over 75%). However, change the load and you get a complete other situation. You have to retune to get back to Walt's condition.

From my experience, many devices with conventional amplifiers (like the valve with pi-filter, or single transistor stages) are now being replaced by other topologies where ZL <> Zout under specified load (as these types of amplifiers are not optimized for maximum gain, but for maximum power added efficiency). I think Tom, KT7ITM also have this experience.

The example given by JC (huge reflection) and my own experience with conventional and high efficiency topologies resulted in my statement that a PA is not a 50 Ohms source. Maybe I had to be more precise to mention the exceptions: forward power control loop as mentioned by Roy, -tuning to maximum output after each change of load, -specially designed negative feedback, -adding an attenuator. The reader can now determine the category for his PA.

In case of doubt use the forward power measurement technique, when it changes under varying load, your amplifier doesn’t behave as a 50 Ohms source.

Best Regards,

Wim

Good day. Sorry for the large extension of this post, my friends...

> My interests lie in understanding the behaviour of transmission lines
> to a level necessary to predict their basic behaviour. I did not find
> that I needed power flux to achieve this so I have not explored it. I
> suspect that you are right and it is an interesting topic.

OK. I understand. I suposse you are more interested in "know how".
When I complained about "the bench" at Richard, I was thinking on so
many "know how" working years in my life. Today, I have more time to
the "know WHYs" and I am trying to take my chance... :>)
A knowledge on Smith Chart (or software equivalent tools) using, solve
most (if not all) of our ham practical and professional situations and
provide enough basic theory for design purposes, I think in such sense
I agree with you about it; however seems to me this topic thread have
dealt a little more in the why's than the how's :>)

Look, several years ago many hams in my country -Argentine- came from
technical schools, I become a ham in my seventeens (1969) when I was a
very young electronic technician student. Here we have three
fundamental educative levels: Primary, secondary (college?) and
terciary (university). In secondary and terciary levels one of the
first matters we study is physics. If we study electronics -on RF
speciality-, only when we reach later study years of each level we
learn transmission lines in the frequency domain with infinite
lattices of RLCG, Telegrafer's equations solution, Smith charts,
impedances, reactances, etc.
If you do not go to study any RF especialities, the only knowledge you
will have about transmission lines will be the physics ones. Physics
models teach us the associated phenomena reffering basically to
electromagnetic fields => we learn about, E field, H field, power and
energy in more basics terms that frequency domain later more advanced
studies. We do not learn typical AC models in basic physics (as you
can see in Resnick-Hallyday books, for example, I can not give you

college's references books because I study from local authors).
In addition at very early physical mechanics courses we learn stationary and traveling waves, superposition principle and late, interference, in optics.
Probably this is not the way to approaching to this topic that medium Ham employ because our natural ansiety to put the rig to work :>D but seems to be a consensus about what is more basic and what more complex in formal pedagogic/understanding approaches to this matters.

May be for that some of us tend to emphasize in directional power flux and other similar "ugly stuff" to analize transmission line questions, Perhaps for this reason it is easy and illustrative to me the Cecil's bridge car analogy about net energy flux, in addition, energy fluxes crossing areas results very intuitive to me because I can easily visualize (imagine) thousands of them hit and cross my body all the time. Sun light and infrared energy flux, light in houses, streets lights, sky diffused light, RF waves from broadcast and Hams, cellular phones, etc. Instead it is not so ease visualize in such intuitive context a single point with a permanent zero voltage (or E field, better) all the time.

Measurement of interference phenomenom requires much more sofisticated and special reductive technics to simplify the problem. One of this technics it is, for example, voltage measurement on a transmission line point with a zero volt pure AC voltage node; but as Cecil et al said, a zero voltage point does not implicate not power flux crossing that point, that is a very known wave interference phenomenom, it is a little easy to visualize it if we remember that fields are "force fields" -fields are forces acting on testing devices- (charges, compass needles, etc), as we learnt in Coulomb laws. Fields being forces let us intuite that having two horses pulling a rock in right angles results in rock moving on a direction resulting of composition of that forces. Seem to be only one force acting in movement direction but are two!. also you can have both horses pulling in opposite directions, then we do not measure any movement and we could think there is not any force acting on the rock!, but our zero force measurement do not implicate there are not two horse pulling the rock! , zero net force it is different of zero force, I think we agree in that.

I believe I undestand your reasoning: P=V*I, => not V, not P!, it is OK. But power not represent the internal system energy, power implicate "energy developed => work/time", you need energy (applied during certain time, then "power") to accelerate a charge, but the charge can have cinetic energy of its own; then, zero volt line point simply are a point where not any energy it is ADDED to the charges. not a point where there is not have (or not can have) preexistent electric energy (current) flowing; why zero volt net force field point would be stop travelling wave energy flow?; think of zero volt line point as a zero potential energy point, not acceleration in it, as the lowest part of a roller coaster...

Incidentally, Poynting vector is defined as "speed of energy flux by unity of area", it is a different thing that power developed on interchange of energy phenomena such electric energy converted to heat or chemical reaction or movement, if we remember what we learn about P=V*I in Joule law (electric to heat transformation) it is a little more evident its transforming (not transport) energy context. Thus, transmited power its different than "developed power" in the other sense (perhaps here my translation not be clear enough). What is your opinion?

Miguel Ghezzi LU6ETJ

PS: I have some more things in my inkwell about models used on our issue but I have to leave it for future postings :>)

One comment here. "Power" is defined differently in pure physics vs engineering. In physics, power requires work to be done. In engineering, one definition of power is energy passing a point in a unit of time, i.e. the energy doesn't have to be used up to be defined as power. One might think of it as potential power waiting to be used. These two quite different definitions of "power" are at the root of a lot of disagreements.

For RF engineers we should probably honor "The IEEE Dictionary" definition: "power - the rate of generating, transferring, or using energy". Since energy cannot be destroyed, all energy that has been generated and is so far unused, is in the process of being transferred. Thus any reflected energy in a transmission line that is in the process of being transferred will be used (lost to heat or radiated) during the transient state following key-up.

the first step of the analysis of this circuit is to combine the 4
voltage sources into a single source, thus rendering point b,d,f
irrelevant. you can then analyze for the currents and voltages
through the 4 resistors easily and show that current flows one way
through all 4 of them equally. circuits 101, 2nd day.

interference is nothing but what you observe after you superimpose two
or more waves. the general principle at work is superposition, giving
it more specific names like destructive or constructive interference
is just describing the result that you observe.

lets see, when steady state is reached you have 100v through 2 50ohm
resistors in series i assume since you say the source provides 100w...
that would mean the current is 1a and each resistor is dissipating
50w.

why would there be power flowing down the line, in this simple dc case
once the voltage in the line equals the source voltage, which in this
perfect case would be after one transient down the line, all is in
equilibrium... and art is happy.

HOWEVER!!! replace that dc source with an AC one and everything
changes, now there are forward and reflected waves continuously going

down the line and back. your DC analysis is no longer valid as it is a very special case. now you have to go back to the general equations and use the length of the line to transform the open circuit back to the source based on the length of the line in wavelengths... for the specific case of the line being 1/4 wave long the open now looks like a short and the current in the source resistor doubles, now making it dissipate 100w!

>the output terminals of the network. Resistance ROS was found to be 50
>ohms.

Quite explicit. Rated power into the rated Z load revealed a
conjugate basis Z match (afterall 50=50) or an image basis Z match
(50=50). The pi-network simply transformed the source/load. Anyone
skilled with the concept of the Smith Chart can immediately follow
that logical construct.

We even get the plate resistance which conforms to within published
specifications for the pair of tubes.

We even get the near classic result of a conjugate basis Z match
efficiency (however, only in the first pass approximation).

How asking the same question:

"Does Walt's data support the evidence of a Conjugate Match?"

migrates into responses to other issues is a strange dance. I ask "up
or down," and everyone wants to vote sideways.

>When you don't touch the plate and load capacitor and change from 50
>Ohms to a load with VSWR = 2, you violate Walt's conditions

I have not the vaguest idea where you got the idea that I changed
anything. The totality of my discussion never budged from steps 1 and
2 and I deliberately and clearly confined all matters there and
repeated them more than occasionally.

>In case of doubt use the forward power measurement technique,

I have, and the data I've asked from you was not intended for some
one-time design for a unique application. This is an Ham radio group,
and the object under consideration is an Ham transmitter. Feel free
to substitute freely among a similar class (frequency range, power
output) such that others might compare their own.

>when it
>changes under varying load, your amplifier doesnï¿½t behave as a 50 Ohms
>source.

This is the most curious statement that eventually comes down the
pike. It is like I am talking to a novice to explain:
"That is what the tuner is for!"

>Maybe I had to be more precise to
>mention the exceptions: forward power control loop as mentioned by
>Roy,

What Roy is describing is nothing close to Walt's hypothesis that I
have confined to a single point observation. No one has advanced
claims made that demonstrate:
1. Constant Z across all loads;
2. Constant Z across all frequencies;

3. Constant Power across all loads;
4. Constant Power across all frequencies.
No competent Ham expects that of any Ham transmitter.

Walt reported a 50 Ohm source Z from a tube rig. I have measured a 50 Ohm Z from two of my own transistor rigs. The difference in technology is not an issue. I have also been responsible for measuring RF power and source/load specifications within the chain of national standards laboratories. Stretching the term RF, this spanned from DC to 12GHz for power levels up to 100W. The sources across the board exhibited 50 Ohms Source Z.

Your own national lab is represented at:
http://www.vsl.nl/
They undoubtedly use the same reference citations as our National Institutes for Science and Technology.

****

Putting the entirety of this discussion aside, and returning to your very special project with an 9 Ohm source of RF at 8 Mhz. How efficient was its operation feeding a 50 Ohm line to a 50 Ohm load? Can you document this with schematics, parts description, and measured data at key points from drain through to the load? This was the level of available resources that came with Walt's discussion.

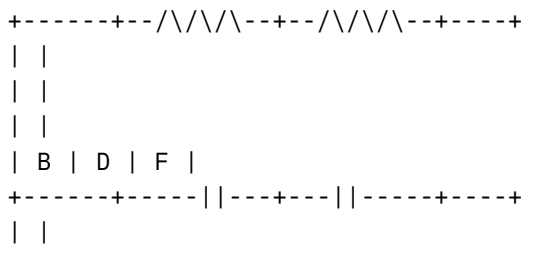
Very nice. How about:



In any case, ABCD do not form a network, being, in fact, two
disjoint networks. All bets are off.

Consider:

There can be current flowing at C and at D, as well as a large voltage difference between C and D, but these have nothing to do with each other and are not an indication of energy flow.

For Cecil, using Google Groups, look for 'Options' and select 'Fixed Font'.

I assume that you do not consider that the problems you propose to be
ones "whose basic premises violate the laws of physics".

Consider then, the problem you propose in http://www.w5dxp.com/nointfr.htm.
A time domain analysis (http://sites.google.com/site/keithdysart/
radio6),
demonstrates that the analysis presented in http://www.w5dxp.com/nointfr.htm
results in the wrong answers.

Perhaps you could locate a flaw in the time domain analysis. Finding a
flaw
would pretty much settle the matter.

Ouch. I can't even get the arithmetic right. You are, of course,
correct. Fortunately, the rest of the examples do not attempt
to compute actual values.

Exactly. And yet, were you to attach a DC-couple directional
wattmeter to the line, it would indicate 50W forward and 50W
reflected (using your corrected numbers).

> in this simple dc case

Not at all. The measurements and computations for forward and
reflected
power that work for AC, work perfectly well for DC, pulses, steps,
or pick your waveform. There is no magic related to AC.

> now there are forward and reflected waves continuously going
> down the line and back. your DC analysis is no longer valid as it is
> a very special case.

Not so. And if it were, at exactly what very low frequency does
the AC analysis begin to fail?

> now you have to go back to the general equations
> and use the length of the line to transform the open circuit back to
> the source based on the length of the line in wavelengths... for the

The transformation properties apply only to sinusoidal AC (note, for
example, that the line length is expressed in wavelengths), but
reflection coefficients and the the computation of forward and
reflected voltages, currents and powers are waveshape independant.

When analyzing in the time domain, use the delay of the line to decide
the values of the signals to superposed. Doing this for sinusoids
will lead to exactly the same results that are expected from, for
example, 1/4 wave lines.

Yes, interference is the result of superposition. Sometimes
superposition results in wave cancellation which is destructive
interference that redistributes the energy in the canceled waves in
the opposite direction in a transmission line - the only direction
that supports constructive interference. The point is that at an
impedance discontinuity in a transmission line, in the absence of a
local source, destructive interference in one direction *requires*
constructive interference in the other direction. That's how a Z0-
match redistributes all the reflected energy back toward the load
while none reaches the source. It is exactly how a 1/4WL thin-film
coating cancels reflections on a piece of non-reflective glass.

The important thing is that a power density equation exists that
predicts the energy flow as a result of superposition.

Maybe if you reviewed "Sec 4.3 Reflection Mechanics of Stub Matching"
in "Reflections", it will be more clear?

Everything I covered is covered in "Optics", by Hecht. If you can
locate a flaw, you need to convince Hecht (and Born & Wolf) to expand
their reference books to cover your pet subjects that they consider
"of limited utility".

Superposition works just fine for voltage and current, but is mostly
invalid for power. Attempting to apply superposition to power will
lead to inaccurate results.

From any circuit analysis, superposition is used to find the voltages
and the currents, and then the resulting total voltages and currents
are
used to compute powers. Doing it in the other order does not work.

I am curious as to what I wrote on the web page that suggested
disagreement with the superposition principle.

I should have mentioned that the two references you provide are
superposing amplitude (i.e. voltage or current) and not power.

It is invalid to try to use superposition on scalar values. There is a particular way to obtain the total power from the superposition of two EM waves. It's called the power density equation and contains an interference term, the sign of which tells us whether destructive, constructive, or zero interference results when the two EM waves are superposed. It agrees perfectly with calculating the total power from the voltage and current end products of superposition. It would explain everything that Roy is missing in his food-for-thought article. I first saw this equation in Dr. Best's QEX article.

Ptot = P1 + P2 + 2*SQRT(P1*P2)*cos(A)

where A is the angle between the electric fields (voltages) of the two superposed waves.

We get the same equation when we square the s-parameter equations.

(b1)^2 = (s11*a1 + s12*a2)^2, where (b1)^2 is the reflected power toward the load.

(s11*a1 + s12*a2)^2 = (s11*a1)^2 + (s12*a2)^2 + 2(s11*a1)(s12*a2)

If it is not obvious, this is the same equation as the power density equation above. The interference term in the squared s-parameter equation contains phasors whose dot product involves cos(A), where A is the angle between those two phasors. More s-parameter information available below - Please note pages 16 and 17 involving powers.

I think the issue is the assertion there is no energy flow when I or V is 0 is where people disagree.

I've tried to show with very simple (EE101) circuits that just because v = 0 at some points in a circuit there is still energy flowing.

But, nobody apparently saw that.

The leap from v=0 to energy flow=0 is the source of contention. Just because the amount of power sourced in one part of a circuit matches the power dissipated in that portion does not mean that all the power sourced in a portion of a circuit stayed in that portion to be dissipated there. The whole rest of the circuit is involved.

When you do your Spice evaluation you only see the _net_ results of the underlaying evaluation and note the _apparent_ lack of energy flow.

By selecting situations that give the results you want, you are reinforcing the misperception. If the generators did not put out identical pulses would you see the same lack of energy transfer?

A linear system, where superposition applies should not change based on minor changes to the signals in it.

Limiting any analysis to steady state sine waves or uniform pulse trains may cause you to reach the wrong conclusions.

> "of limited utility".

Let us follow the chain:
1. Hecht writes a book on OPTICS that includes some models.
2. Cecil reads the book.
3. Cecil interprets his readings.
4. Cecil applies his interpretations of the models to transmission
lines.
5. Cecil draws some conclusions on the behaviours.
6. Keith, using basic circuit theory, reflection coefficients and
analysis in the time domain, shows that Cecil's conclusions do not
align with expected behaviours.
7. Cecil says any disagreement with Cecil's conclusions is a
disagreement
with Hecht.

I suggest the error is more likely in steps 2 to 5; Hecht is, after
all,
well respected.

In particular, 4. seems like a candidate. It is quite possible that
Hecht understood the limitations of his models and that these models
do not align with the detailed behaviour on a transmission line,
though
they might be completely adequate for the behaviours with light that
Hecht was addressing in Optics.

One must always be careful when applying a model in a different
domain.

Cecil

I must have missed the posting where you proved RF waves do not obey the *average* power density (irradiance) equation from "Optics", by Hecht. Neither Hecht nor I have ever said anything about instantaneous virtual power except that it is "of limited usefulness". Nothing you have posted about instantaneous virtual power has disagreed or disproved anything that I have said about *average* power where I simply quoted Hecht. I suspect that your instantaneous virtual power must necessarily obey the conservation of energy principle but I am not going to waste my time trying to prove it. Hecht and I seem to agree 100% that *average* energy flow obeys the laws of physics.

May I suggest that you read "Optics", by Hecht and post anything with which you disagree. I, and others, stopped taking you seriously when you said that an equal magnitude of the forward Poynting vector and the reflected Poynting vector proves that zero energy is crossing the boundary (without adding that it is zero NET energy). You have probably ruined your technical reputation with such nonsense.

I had to run an errand and, as usual, the answer popped into my head.
The problem has to do with the definition of "power". If, in a flat
system, one measures 100 watts at 100 points between the source and
the load, does that mean that there are 10,000 watts of power
available to be dissipated or radiated? Of course not! That is your
conceptual error.

Keith, your instantaneous virtual power is not *real* power until it
is dissipated (or radiated). Thus your instantaneous virtual power is
not required to obey the conservation of energy principle and all bets
are off. If your instantaneous virtual power seems to violate the laws
of physics, it is simply because you are counting it too many times or
too few times.

Instantaneous virtual power is *absolutely irrelevant* until it is
dissipated or radiated. In my resistive-source/resistive-load (no
radiation) example, nothing of value actually happens until power is
dissipated in one of the two resistors. I have accounted for all the
power being dissipated in the two resistors. Your V(t)*V(t)
instantaneous power doesn't matter unless it is being dissipated and
surprise!, it is not, i.e. your instantaneous power doesn't *count*
until it is dissipated. Please feel free to try again.

basically, RF loss is not a controlled parameter for manufacturing.
Sometimes it might be fine, other times not.

The Tesla Coil builders use lots of PVC pipe as coil forms (as well as
things like cardboard concrete forms: Sonotube(r)) and there is huge
variability in dielectric strength. I would imagine that RF loss also
varies substantially.

If you're really obsessing, the loss varies quite strongly with
humidity. PVC readily takes up and releases moisture from the atmosphere.

Good evening. (sunny and cold day, here)

> Superposition works just fine for voltage and current,

And electromagnetic waves... We also study TL in physics with a
electromagnetic model (E-H fields).

> but is mostly
> invalid for power. Attempting to apply superposition to power will
> lead to inaccurate results.

Yes. As Cecil pointed, power not apply to superposition because it is
a scalar magnitude.

> I am curious as to what I wrote on the web page that suggested
> disagreement with the superposition principle.

Because my interpretation of this sentences on the wave page:

> What happens when the signals from two identical generators
> at each end of a transmission line collide in the middle?

Term "collide" without quotes suggest (to me) interaction (as particles). I learnt travelling waves do not "collides" in space (or linear mediums), simply they crossing each other (as ghosts).(I do not be sure about this translation)
or, quoting UCLA web page note, "Wave maintain their integrity upon overlapping (without themselves being permanently changed)".

> Does energy cross the midpoint of the transmission line?
> .....
> The plot shows that the voltage in the middle of the transmission
> line is always zero (that's femtoVolts on the left, not a bad
> representation for 0 in a simulation). Recalling that Power =
> (Volts times Amps), if the voltage is always 0, then there
> is no power. With no power, no energy is crossing the
> middle of the transmission line.

My interpretation of last sentence (and reading technical controversy with Cecil and K1TT in thread) make me think that it does not match to superposition principle (except when there are not any travelling waves in system, of course). (I do not considered here spice application to travelling wave model issues).

Please tell me if you agree with Java applets linked -applied to TL travelling waves- to clarify my understanding of your proposition.

Hi OM,

Thanks. Clear answers to clear questions are rare.

So:
2ï¿½ "Walt's data does support evidence of a Conjugate Match"
and
ï¿½ "Walt's data does not support evidence of a Conjugate Match"

As for confusion - the split vote must be proxy for the "silent
majority." Or, that majority cannot risk exposure. Shame? The only
issue is either with the data or the expression "Conjugate Match."
None seem anxious to avoid discussion of the expression - in fact that
conversation runs like a party line.

On the other hand, challenge the data? The numbers were cribbed? The
test gear was in the "off" position during a test? No. The data
seems to make sense. Competing data for the same initial conditions?
Hark! The scientific method rises from slumber with interest.

Nope, nada, negatory, no way, not going there.

Scientific method returns to its narcoleptic state.

Source record: 9155

If you have a resonant antenna, supposedly all of the power is radiated.

(SWR 1:1)

If you have a nonresonant antenna, some of the power is reflected back to
the transmitter.

(SWR > 1:1)

If you connect a tuner and it is "tuned", none of the power is reflected
back to the transmitter.

(SWR at transmitter 1:1, at antenna still > 1:1)

Obviously it has to go somewhere.

Where?

If you are designing a tuner, where would you design it to go?

Thanks in advance

Geoff.

news:slrni0vn5p.3ik.gsm@cable.mendelson.com:

Geoffrey,

I have bad news for you, your post is based heavily on misconceptions,
archetypal ham myths even.

I wrote a short article entitled "A simple VSWR analysis without mirrors"
at http://vk1od.net/blog/?p=1259 , which analyses a mismatched line example
without resorting to dodgy concepts often (and almost exlusively) employed
by hams. The article does deal with why there is a reflected wave, and the
result of that reflected wave on line loss and transmitter loading.

IMHO, you would do best by starting with a reputable text book, and
studying the topic. Certainly, the S/N ratio in ham forums is low, 'facts'
seem to be determined by vote, and your wrong concepts are more likely to
be reinforced than seriously challenged.

A antenna at resonance does not necessarily match the feeder impedance !
The whole idea of a tuner is to make one end match the other.
Stating a VSWR of unity implies a 50 ohm measurement system, which an
antenna at resonance rarely is.

All of the power produced by a transmitter is either radiated or
dissipated as heat, period. But you'll never understand where the
"reflected power" goes until you understand where it comes from.

Consider a 100 watt transmitter connected to a 50 ohm dummy load or
antenna via a half wavelength of 50 ohm lossless transmission line.

The transmitter sees an impedance of 50 ohms resistive.
The transmitter delivers 100 watts to the transmission line.
The transmission line delivers 100 watts to the load.
The load dissipates 100 watts.
The VSWR on the line is 1:1
The "forward power" in the transmission line is 100 watts.
The "reverse power" in the transmission line is zero.

Ok so far? Now replace the transmission line with one having 200 ohm
impedance.

The transmitter sees an impedance of 50 ohms resistive.
The transmitter delivers 100 watts to the transmission line.
The transmission line delivers 100 watts to the load.

The load dissipates 100 watts.
The VSWR on the line is 4:1.
The "forward power" in the transmission line is 156.25 watts.
The "reverse power" in the transmission line is 56.25 watts.

By changing the line impedance, we somehow created an extra 56.25 watts of "forward power". Neither the transmitter nor the load was aware of this wonderful event, since the transmitter sees the same load impedance as before, and the load sees the same source impedance. The transmitter is delivering exactly the same amount of power as before, and the load is dissipating the same amount. (If the transmission line had loss, it would have increased very slightly, but probably not enough to measure, and certainly much, much less than 56 watts.)

Likewise, neither the transmitter nor the load knows anything about the new "reverse power" which was created at the same time.

So the answer to your question is that the "reverse power" goes to wherever the new excess "forward power" comes from. Once you figure out where that is, you'll have a better understanding of the topic than nearly everyone who has been arguing on this forum about it for years.

As for a tuner, it has the magical property of having different amounts of "forward power" and "reverse power" at its input and output when the amount of actual power flowing is the same on both sides (neglecting tuner loss). So it can create or destroy "forward power" as well as "reverse power" by a simple twist of its knobs. Little does the tuner, transmitter, or load know that as soon as "reverse power" is created, interminable arguments will take place debating about where it goes.

I now return you to your regularly scheduled programming. . .

Hi Geoff,

You would put it closer to the antenna.

>If you connect a tuner and it is "tuned", none of the power is reflected
>back to the transmitter.
>Obviously it has to go somewhere.

From the perspective of the transmission line in between, when it hits
the discontinuity of the tuner, it is reflected back to the antenna.
The antenna drains away some of that power (just as it did in the
original pass). The process repeats (the antenna is still partially
reflective) and is further sustained with new cycles of energy.

There are finer details that shift these dynamics.

Differentiate between an antenna that happens to present the wrong non-reactive resistance... the tuner is just a transformer (whether done with linked magnetic fields, or by a narrow band matching network of Ls and Cs)

and an antenna that presents a reactive feedpoint impedance.
In this case: energy circulates between the tuning network and the antenna.

Say your antenna presents a Z that is inductive and you put a parallel capacitor across the feed to exactly cancel the "inductance". What's really happening is that you have the equivalent of an LC tank where the energy moves back and forth between L and C every cycle. In the classic LC, the energy moves between the magnetic field of the L and the electric field of the C. In the antenna case, it's somewhat more complex: the antenna stores energy in the near field in both electric and magnetic fields.

That answers the question...
The problem is that nothing is lossless, so as it moves, there's a loss. If it's a resistive loss, it goes as I^2, so doubling the current results in 4 times the loss. And, if you have an antenna with high stored energy (about which more, later), this square of the current means bad news.

Many antennas don't have an explicit separate matching network, but do the cancelling by doing it within the antenna structure: say by changing element lengths, etc... so now that "circulating current" is circulating between different parts of the antenna.

In fact, the ration between that stored energy and the amount flowing "through" (i.e. radiated away) is related to the directivity of the antenna: high directivity antennas have high stored energy (large magnetic and electric fields): the ratio of stored to radiated energy is "antenna Q" (analogous to the stored energy in a LC circuit leading to resonant rise).

So, high directivity = high stored energy = high circulating energy = high I2R losses.

It circulates between tuner and antenna.

> identical pulses would you see the same lack of energy transfer?

Of course not, because then there would be. And the measurement of
voltage and current would show it to be so. P=VI holds.

If one selects a V and I that are not appropriately related then one
does not compute a useful power, though the units may still be J/s.
As an illustrative example, if I measure the voltage across my stove
and the current through my light, I can multiply them together to
get watts, but it does not mean much.

> A linear system, where superposition applies should not change based on
> minor changes to the signals in it.

Agreed. The computations done with the altered signals will
successfully
predict the altered outcome.

> Limiting any analysis to steady state sine waves or uniform pulse trains
> may cause you to reach the wrong conclusions

Yes, and no. I suggest that the models that are claimed to
successfully
predict the behaviour for sinusoids should also successfully predict
the
behaviour for simpler examples. Otherwise the models are suspect. So I
use the simpler examples to show that the models break down.

Ahhh, so you are only claiming that 'on average', the energy does not
enter the PA or 'on average' the energy is reflected.

The finer grained time domain analysis, reveals that some energy does
enter the PA, but that it comes back out again to keep the average the
same.

So if you want to live with the coarser, less complete models, that
is
fine as long as you understand the limitations of your model. It would
be good if you were to articulate these limitations to the readers
to reduce confusion.

Of course, if you are happy with averages, it is not obvious to me
why you want to bother with separating the signal in to forward
and reflected. Why not just use the overall average energy flowing
towards the load.

Not quite. It does not apply to power because it does apply to
voltages.
If one doubles the voltage, one gets 4 times the power. There is no
way to make superposition (which is simply addition) simultaneously
work
for voltage and power.

As for scalars... Superposition works quite fine for circuit analysis
with scalars.

Superposition is a mathematical trick that allows the solution of
the problem. It does not mean that the pulses pass through each
other, though that is one of the visualizations. Consider a point
on the line where the current is always 0, no electrons cross
this point nor does any energy. Did the pulses cross through
such a point? The voltage envelope appears to, but does that mean
the pulse did?

I have no issues with the applets. They show voltage waves crossing each other and appropriately use superposition to derive the results.

Like many optical illusions, there are multiple ways to visualize what is happening. The second one for example can also be seen as the two pulses bouncing off of each other. The response would be identical if the transmission line was cut at the point of collision.

These two simulations do not claim to show energy moving all the way down the line in both directions, nor do they superpose powers. So they look fine.

Hello Keith:

I believe I just understand where is the problem You are talking
about "Superposition Theorem" of circuit theory and we are talking
about "Superposition pinciple of waves". There are not the same stuff.
Please read this page from "Physics for scientists and engineers with
modern physics" book to aliviate my translation :>)

http://books.google.com.ar/books?id=wQCMC3ryYzkC&pg=PA501&lpg=PA501&dq=%22superposition+principle%22+%22traveling+waves%22+physics+-quantum&source=bl&ots=SK0b7V6O6y&sig=HzwcgC2DJnXKce2QZliOYq8yhDw&hl=es&ei=-2AQTLqpM8P98Abx_ciFBg&sa=X&oi=book_result&ct=result&resnum=5&ved=0CDUQ6AEwBA#v=onepage&q=%22superposition%20principle%22%20%22traveling%20waves%22%20physics%20-quantum&f=false

Uf, what a large link!! If do not works search on page 501 of Google
books with the appointed title.

Note => "Two travelling waves can pass trough each other without being
destroyed or even altered". (Op. Cit.). (Please pay attention to pond
example).

The applet there do not represent an opticall illusion, You can experiment with different shape opposite end launched pulses in a rope to verify that do not collide but pass through each other. It is a usual student laboratory work on applied physics.

Before I forget... Here is early mornig and I am ready for bed (I'm nocturnal habits). I want give a QSL to Cecil's comment on Maxwell article and Joe's example in CC. Also, noblesse oblige, I recall that Cecil make this comment in a very early post in this thread:

> Yes, standing waves are hard to visualize, but there is indeed
> same- cycle interference involving forward waves and reflected
> waves. There is a certain delay from the source signal to the
> load and back that can be calculated if one chooses. The
> wave reflection model is closer to Maxwell's equations than
> is the lumped-circuit model where EM waves propagate
> instantaneously.

Pointing to differences between lumped constants circuit theory models (superposition theorem) and TL issues. I aknowledge his linked page
=>
http://www.google.com/url?sa=D&q=http://www.ttr.com/corum/index.htm&usg=AFQjCNGKvyE7gzlWnW7706V-3Vix1MXnrA
where it said:

"There are no standing waves on a lumped element circuit component. (In fact, lumped-element circuit theory inherently employs the cosmological presupposition that the speed of light is infinite, as every EE sophomore should know. See, e.g., - Electric Circuits, by J.W. Nilsson, Addison-Wesley, 1983, p. 3.)"

Probabily Cecil had in mind this controversy when I submitted my question to this newsgroup. He will correct me if I am wrong.

Thank you very much, and now, I am go to ZZZZZZZ...!

Miguel

Ah! Cherchez la femme. We did a lot of walking around town (stayed
in the Emperador across from Estaciï¿½n Retiro) and there were certainly
crowds of them on Av (Calle?) Florida and along Av 9 de Julio (24
lanes of traffic as I remember with trying to cross from the Opera
house Teatro Colï¿½n). In the back of my mind was that Buenos Aires
enjoys the world's highest pedestrian death rate. One large truck
replaced it horn with the sound of someone screaming. (The memories
are starting to flood back.)

It was strange to see Spanish headlines about the capture of Saddam
Husein in his spider hole. An out-of-America experience much like the
evening when I was standing on the quay in Acapulco, waiting for the
Liberty launch back to my ship, and a wave of talk spread through our
group that Nixon had just resigned.

However, returning to pretty girls, when I was in Caracas ten years
ago, I was told the poor lived up in the hills that surround the city
like a fish bowl and the girls got plenty of exercise climbing them.
Gave them Miss Universe figures.

As for Buenos Aires hospitality, too much food (huge steaks) at the
wrong hours. When we went to a restaurant at 9PM, it was like we were
arriving for high tea. How gauche of us. Later, we were satisfied to
enjoy empanadas in the late afternoon and call it dinner. We also
took the train from Estaciï¿½n Constituciï¿½n down to La Plata to see the
Catedral. Dinner nearby was Wiener Schnitzel. Enjoyed walking
through Recoleta (and seeing the cemetery). Also got out to Abasto to
see Carlos Gardel's neighborhood (love his Tango, his singing gets
better every year).

It was great!

Let's be careful to point out that "forward power" is a measurement
at a fixed point on a transmission line of the rate of flow of the
forward energy which is traveling at the speed of light in the medium.
Same concept for "reflected power" - reflected energy flowing in the
reverse direction at the speed of light in the medium. EM waves cannot
stand still.

It's easy to figure out where the excess forward energy comes from
especially in an ideal lossless system which I will assume for the
rest of this posting. Consider the following thought experiment. An
ideal lossless system with a one-second long Z0=300 ohm feedline. Why
one-second long? Because the watts (joules/second) and the joules will
be the same magnitude, i.e. If it's a matched line with 100 watts of
forward power, it is easy to show that a one-second feedline has 100
joules of energy in it that has been sourced but not yet delivered to
the load - like a delay line.

Here's an example of a Z0-matched system with an SWR of 6:1 on the
Z0=300 ohm feedline. *Steady-state* conditions are: forward power =
204 watts and reflected power = 104 watts. Power delivered to the load
= 100 watts. There is a steady-state Z0-match at '+'. Zero reflected
energy reaches the source, i.e. the SWR on the 50 ohm line is 1:1.

100w source---50 ohm line---+---1-sec-long 300 ohm line---50 ohm load

During the transient key-down state, the source supplies a number of
joules to the transmission line that do not reach the load. At the
beginning of steady-state that value is 204 joules plus 104 joules
equals 308 joules.

When steady-state is reached there are 308 joules of energy "stored"
in the one second long transmission line that have not been delivered
to the load. Only after the transmission line is charged with steady-
state energy does the load start to accept the same amount of power as
is being sourced. There is no magic here - just a simple accounting
for all the energy. Why otherwise intelligent, educated RF engineers
cannot perform that simple second-grade math is a subject for another
thread.

During steady-state, there are 308 joules of energy "stored" in the transmission line that are performing the Z0-match function. There are 204 joules in the forward wave and 104 joules in the reflected wave. Since RF cannot actually be stored as in a battery, this energy is moving at the speed of EM waves - the speed of light in the medium. 104 joules/second is continuously being reflected at the load. 104 joules/second is continuously being redistributed back toward the load at the Z0-match.

At key-up, steady-state ends and the key-up transient state occurs. During this transient state, all of the 308 joules in the forward wave and reflected wave during steady-state will be dissipated. During the key-down transient state, 308 joules are stored in the one second long transmission line. During the key-up transient state, the 308 joules are dissipated. For those who feel overwhelmed, it is just simple second-grade math

In a Z0-matched system, the entire analysis can be performed using an energy analysis instead of a voltage analysis. The common way to analyze the above system is to assume that 70.7 volts is present on the 50 ohm side of the Z0-match with 1.414 amps flowing into the Z0-match. But with only an energy analysis, we can reverse-engineer the voltage and current conditions at any point in a Z0-matched system.

Fact of Physics: There are exactly enough joules of energy in the mismatched transmission line to support the forward wave power and the reflected wave power. It's not magic nor rocket science. Anyone willing to count the joules that have not reached the load will realize that the energy in the forward and reflected waves consists of real-world joules that cannot be swept under the rug just because some alleged RF guru is ignorant of the laws of physics.

Here's a simple math problem for all of the readers having trouble with this concept. On 10 MHz, we have a 50 ohm antenna being fed with one wavelength of lossless 300 ohm line from a 100w source. During steady-state, how many microjoules of energy are "stored" in the transmission line that have not yet reached the load? How are those microjoules split between the forward wave and reflected wave?

Just a nit: A certain magnitude of energy circulates between tuner and antenna. Experiments with TV signal ghosting prove that it is not the identical energy, just the same magnitude of energy.

http://www.w2du.com/Appendix09.pdf

A purist might argue that, like a lossless transmission line, an ideal
conjugate match cannot exist in reality because of resistive losses
and non-linearities.

What might be a more accurate statement is: By definition, Walt's data
supports the evidence of a real-world Conjugate Match. Walt has
certainly defined in detail what he means by a "(real-world) Conjugate
Match".

Keith, virtually everyone (except you) knows that English is a
contextual language and that the entire context cannot be repeated
every time a sentence is uttered. You know and I know that the context
is EM waves. The obvious context of my statement is: "It is invalid to
try to use EM wave superposition on scalar values, since scalar values
are not EM waves."

If you feel forced to resort to crap like that, it indicates that you
have already lost any argument.

Of course, you already knew that because I have never said otherwise.
I have stated my opinion more than once that instantaneous (virtual)
power is not worth discussing. Here is what I said on my web page:

"Please note that any power referred to in this paper is an AVERAGE
POWER. Instantaneous power is beyond the scope of this article,
irrelevant to the following discussion, and "of limited utility"
according to Eugene Hecht. [4]"

I have an ample library and cannot find any reference to instantaneous
(virtual) power other than it is "of limited utility", as Hecht noted.
Most of the references imply that paying close attention to the
reality of instantaneous (virtual) power can lead one down a primrose
path to false assumptions.

> The finer grained time domain analysis, reveals that some energy does
> enter the PA, but that it comes back out again to keep the average the
> same.

So what? If it is not dissipated or radiated, it doesn't matter to
anyone (except you).

> It would
> be good if you were to articulate these limitations to the readers
> to reduce confusion.

I have always said that I was talking about power dissipation in a
source resistor or load resistor (or radiation), but you already knew
that. I have said that instantaneous virtual power is irrelevant and
not worth discussing.

Here is a question for you. Given that P(t)=V(t)*I(t), we measure 10
watts at each of 10 points within a single cm., five just inside a
source and five just outside the source. Does that mean we have 100
watts in that single cm.? What is the physical meaning of being able
to measure an infinite amount of power given an infinite number of
measurement points?

It probably should have said: "By a (possibly invalid) definition only, there are no standing waves on a lumped element circuit component, even though standing waves might exist in reality". Note that Dr. Corum is NOT saying that there are no standing waves. He is simply repeating the false assumptions of the lumped-element circuit model. In his other paper, he says that if a circuit is electrically longer than about 15 degrees and phase is important, the lumped-element circuit model should not be used.

Any lumped-element circuit analysis can be caused to fail simply by increasing the source frequency.

You wrote:
"You can use any insulated wire"

I agree.
I hound in tracing the location of large buried undrground pipelines, the "cooperative method", a transmitter attached to the pipe with a receiver sensing the signal on the pipe worked best. Due to ground characteristics, the lower the frequency, the better. I used 12 Hz.

My transmitter used cpmplementary symmetry power transistors in its output which fed a 400-Hz Variac which proved to work well as a variable impedance matching transformer to the pipeline. Oscillator-amplifier and Variac were about the size of a bread box and weighed much less than the 12-volt car battery which powered them.

The receiver was a common relay coil with an iron core which fed a transistor amplifier which had its output rectified and metered. The coil was attached to a stick which served as a wand. Divers used the coil in rivers and oceans where it followed the signal very well, as on land.

The strongest signal was when the core pointed directly to the pipe, and checking the distance to either side of the pipe the signal could be well received gave an estimate of the depth of the ground covering the pipe, usually 6 to 8 feet in our case. I could go miles down the pipe before the signal faded (once 8 miles).

I don`t know how applicable any of my pipeline experience is to animal burrows but it works well with tracing buried conductors or wires in walls for that matter.

Our pipelines also had rectifiers for cathodic protection and I also keyed these on and off at low frequency to provide a unique signal to follow.

Best regards, Richard Harrison, KB5WZI

only as you monitored the initial transient. once the transient has
passed there is no power flowing in the line. to drive power requires
a potential difference, without potential difference there is no
current and no power.

>
> > in this simple dc case

> or pick your waveform. There is no magic related to AC.

ah, but there is... in a sine wave the voltage never stops changing so
there is always a potential difference driving the wave along the
line. with DC you can reach equilibrium in one transit of the cable,
assuming it is lossless and the source and/or load is matched to the
line. otherwise you have to do the infinite sum to approximate the
steady state as for any other transient. complex waveforms get ugly
since they are infinite sums of sine waves, though for lossless and
dispersionless cables they aren't too hard to handle. The magic of a
single frequency AC source is it lets us use simplified equations that
make use of the sinusoidal steady state approximations... this is what
lets us do things like s parameters, phasors, E=IZ, and cecil's simple
power addition equation, without the need for messy summations and
other more detailed calculations.

none, there is no magic cutoff, its just how close you want to look at
it.

true, another simplification made possible by the sinusoidal steady
state approximation.

> but
> reflection coefficients and the the computation of forward and
> reflected voltages, currents and powers are waveshape independant.

only as long as the loads are perfectly resistive and linear. real
loads often change impedance with frequency and so distort the
reflection of complex waveforms. use a scope with a good risetime and
a decent fast rise time pulse and you'll see it.

Real loads also change Z with power - especially dummy loads. As a
real load has some trait of dummy load in it (loss) the degree of Z
change is in the degree of temperature change.

Hello folks. (I am learnig new greetings...)

Hi Cecil:
Yesterday I was making some calculations based in your article "An energy Analysis of a Simple Ideal Source, Part:1 Zero Average Interference"
I have checked your and Roy results using three methods: Mathematical solution using the TL Zin obtained from clássical formulas.
Spice simulation with equivalent lumping element resulting of the above cited formulas, and Spice simulation with a RG8U TL loaded with RL's of your and Roy examples..
In all cases results agree between different methods and with your examples (I do.not want to seem pedantic with this last comment ;>))

For this discussion would be relevant the results corresponding to sixth column of your article using a quarter wave line.
They are: 0 - 8 - 22 - 50 - 88.9 - 128 and 200 W (190 W the last one with Spice TL simulation).

Since the refflection coefficient has not changed, if I do not misunderstood the premises, quarter wave line PRs do not seems agree with the hipothesis of Pref adding in Rs with Pfor. I think that is what Ro. Lewallen denote in his "Food for thought: Forward and reverse power" example.
Frankly, I think there are somthing wrong in my interpretation because you (all) should have already performed these checks. I remember you have said something about that your work (article) was not finished yet. I confess actually I have not yet entirely clear your differences but I hope to capture it more accurately.

73 - Miguel LU6ETJ

PS: Hey Richard, I'm glad you liked our city, girls and steaks :>) well you like Gardel (me too) and I like so much your old and classic jazz music. Billie Holiday... she is one of my favorites.

Hi Miguel,

I was in the Navy from 1968 to 1975. Our president Richard Nixon
resigned from the presidency in 1974. My ship was in transit between
Charleston, South Carolina to go to the naval ship yard for overhaul
in Bremerton, Washington (state), near Seattle (where I live).

On the way, we spent 5 days in the harbor of Acapulco. We were
"anchored out," which means resting at anchor in the bay instead of
tied up at a pier.

The only way to get back and forth was by a smaller boat (carries
about 75 people). That boat is called a launch. That name is
qualified with Liberty because those who used it were going on
Liberty. In the Navy, Liberty means "time off" or "free time," which
means we can leave work and do what we want to until 0800 the next
day. If we have to be back by midnight, it is called "Cinderella
Liberty."

I was one of the senior Metrologists in the Fleet Electronics
Calibration Laboratory aboard the USS Holland, AS-32 (now tied up in
retirement in Bremerton). I did precision measurement and calibration
of RF standards and maintained a Cesium Beam Standard (atomic clock)
that set the time for the "Boomers" (nuclear submarines). Later,
after the Navy, I added physical standards (length, pressure, tension,
temperature, torque, smoothness, incline...) to my resumï¿½.

I try to catch as many movies from Argentina as possible (I like
Ricardo Darï¿½n as an actor, and love "Nueve Reinas"). One of my
degrees is Cinema (the other is English). Another title I like (since
it is about an out-of-work programmer) is "Una Sombra ya Pronto
Serï¿½s." Sometimes that title works here too. Hï¿½ctor Olivera, the
director, has done some interesting things.

this is a relationship i haven't heard of before... and would be very
wary of stating so simply. it may be true for a specific type of
antenna, MAYBE Yagi's, MAYBE rhombics or or close coupled wire arrays,
but some of the most directive antennas are parabolic dishes which i
would expect to have very low Q and extremely low losses. you could
also have an antenna with very high Q, very high i^2r losses, but very
low directivity, so i would be careful about drawing a direct link
between the two.

Well Richard, since the example discussion implies lossless line, you know that zero power is dissipated in line losses.

Assuming that you are talking steady state...

If literally, you changed the line length in Roy's example to an electrical quarter wave, then the transmitter will see a load impedance of 800+j0, and it will develop exactly the same power in the actual load (quarter wave 200 ohm line+50+j0 load) as it would in a 800 ohm resistor connected to its output terminals. Since the line is lossless, 100% of the actual transmitter output power is absorbed by the load, dissipated if the load was a resistor. If you were to plot the instantaneous power at the transmitter output terminals vs time, it would always be positive, ie there would not be a reactive component.

The transmitter output power is probably different to that developed in a 50+j0 load for several reasons, but there is not enough information to determine that output power.

Of course, a practical line has line loss, and the heat generated under standing waves varies along the line (ie W/m is not constant), and the impedance seen by the transmitter will be a little different (including being reactive) due to the fact that Zo is not real, the VSWR is not 4, and effects of line attenuation, so actual transmitter power may be a little different.

Thank you, Owen.

Do your comments apply to a transmitter designed/adjusted for, and expecting a 50 + j 0 ohm load?

IOW, if the net output power of such a transmitter (which equals that dissipated in the load) probably is different with such a mismatch, do you expect the reason for that to be related to "reflected power?"

> with Spice TL simulation).

I'm sorry, Miguel, using a "quarter wave line" is a mistake. You should be using a lossless 1/8WL line. The results in my article are based on a 1/8WL (45 deg) lossless line, NOT on a 1/4WL (90 deg) line. *Please re-run your Spice simulation using a 1/8WL line* and report back to us. When the line is 1/8WL long, the reflected wave arrives back at Rs 90 degrees out of phase with the forward wave and cos(90) = 0, so the interference term is zero and all the reflected power is dissipated in the source resistor. For the special case where cos(A)=0, i.e. the interference term is zero, the power density equation reduces to: Prs = Pfor + Pref + 0

Nowhere in my article did I use a 1/4WL line so please don't say that your Spice results disagree with my chart. It is perfectly understandable that your 1/4WL results do not agree with my 1/8WL results.

NO! NO! NO! the difference is not due to 'reflected power'... any
difference is due to the impedance change seen by the transmitter at
its terminals.

A VERY important method of analyzing sinusoidal steady state response
of a system like a transmission line with a load on the end takes the
load impedance and transforms it using the transmission line equations
(with or without loss) back to the source terminals and then replacing
it with an equivalent impedance. as long as the load is constant and
linear this is a well known and easily proved substitution. you can
then solve for conditions seen by the source ignoring the length of
the line and load and using only a lumped impedance, therefore any
reflected wave is irrelevant when analyzing the response of the
source.

If the "forward" power that can be generated by a transmitter is
dependent on the degree of match of the output load to the load
specified for that transmitter, would that not mean that there would
be little/no risk of damage to the transmitter if it was operated into
a load with ~infinite SWR relative to the load it expects, such as a
short or open directly at its r-f output connector?

Please let's be careful to give all the details. The *virtual*
impedance, the ratio of Vtotal/Itotal, seen by the transmitter at its
terminals is:

Z = Vtotal/Itotal = (Vfor + Vref)/(Ifor + Iref)

where all math is phasor (vector) math. Vref and Iref are components
of the reflected wave. So the mismatch is certainly related to the
magnitude and phase of the reflected wave. If the Z0 of the
transmission line is the impedance for which the transmitter was
designed, we can go as far as to say that the reflected wave causes
the mismatch, the virtual impedance that deviates from the Z0 of the
line. Before the reflected wave arrives back at the transmitter, the
transmitter sees the Z0 of the transmission line. The mismatch
develops when the reflected wave arrives.

i wouldn't call it a 'virtual' impedance, it is a very real impedance.
it is the steady state impedance seen by the transmitter at its output
terminals. once the transient response rings down the waves in the
line beyond the terminals are irrelevant and the constant impedance
can be used to calculate the voltage, current, and power in the
source. in the steady state (which except in special cases is
entirely adequate for amateur use) the mechanism of generating that
impedance is irrelevant, waves or not it can be represented by a
constant value and the source won't know the difference.

It can be very close, though, if the system is designed/optimized
properly.

Below is a link leading to the r-f pulse measurement of a UHF TV
broadcast antenna system that I made as an RCA field engineer some 35
years ago. The incident and reflected waveforms are very similar.

The Z-match of this antenna was optimized to the transmission line
using a variable transformer at the input to the antenna, which
antenna was installed atop a ~ 1,500 foot tower (note the ~3 µs round
trip for the reflection, at ~492 feet/µs).

The H.A.D. of this sin^2 pulse denotes an r-f bandwidth approximately
as great as can be carried by a 6 MHz analog US TV channel.

> i wouldn't call it a 'virtual' impedance, it is a very real impedance.

Yes, it meets the (B) non-dissipative definition of impedance from "The IEEE Dictionary". It doesn't meet the (A) dissipative definition and it is not an impedor as it only exists as a V/I ratio. That's why I call it a virtual impedance. There is no resistor, there is no inductor, and there is no capacitor. There is only a V/I ratio caused by something else.

> it is the steady state impedance seen by the transmitter at its output
> terminals.

And it is a V/I ratio caused by the superposition of the forward wave and reflected wave, i.e. it would NOT be the same impedance without the reflected wave. That fact of physics is undeniable.

When we have an actual impedor, i.e. a resistor plus an inductor or a capacitor, the voltage/current ratio is caused by the impedor. When we have a virtual impedance, the cause/effect procedure is reversed and the impedance is caused by the voltage/current ratio which may (or may not) contain both forward and reflected values.

For the two definitions of impedance, (A) and (B), given in "The IEEE Dictionary", cause and effect are reversed.

Let's take an example. Assume a 50 ohm load resistor fed with 1/2WL of 300 ohm lossless line. If we assume a 100 watt (50 ohm) source, the forward power will be 204 watts and the reflected power will be 104 watts.

100w Source----1/2WL 300 ohm feedline----50 ohm load

In the feedline, a forward power of 204 watts is a forward voltage of 247.3 volts and a forward current of 0.825 amps.

In the feedline, a reflected power of 104 watts is a reflected voltage of 176.6 volts and a reflected current of 0.589 amps.

The reflected voltage is 180 degrees out of phase with the forward voltage at the transmitter, so the superposed voltage at the transmitter is 70.7 volts. The reflected current is in phase with the forward current at the transmitter so the superposed current is 1.414 amps. Since everything is either in phase or 180 degrees out of phase, phasor addition is not needed. So I repeat, the impedance seen by the transmitter is:

Z = (Vfor - Vref)/(Ifor + Iref)

Z = (247.3 - 176.6)/(0.825 + 0.589)

Z = 70.7/1.414 = 50 ohms, NON-DISSIPATIVE!

It is clear that the superposition of the forward wave with the reflected wave is the CAUSE of the 50 ohm impedance. That particular impedance cannot exist without the effects of the reflected wave.

Using a math model for answers to problems for so long that one comes to believe that the model dictates reality is a major contributor to the myths and old wives' tales that exist in amateur radio today. It's time to get back to the basics even if it causes a few old rusty brains to be put in gear for the first time in decades.

We've had this discussion many times before, but with no apparent change in your perceptions of the nature of "reflected power".

But why would you expect the "reflected power" to have a different effect when the transmission line is a quarter wavelength than when it's a half wavelength? Can you write an equation giving the supposed dissipation caused by "reflected power" as a function of transmission line length?

If reflected power is fictitious, and the number wavelengths of transmission line of any random impedance compared to the load connected to it makes no difference in the load seen by the transmitter, the output power produced by the transmitter, and the power dissipated in the far-end termination, then what is the reason you chose a 1/2 wavelength of transmission line in your quoted post?

"The IEEE Dictionary" has no such definition. Those are my words
adopted from "Reflections", by Walter Maxwell, and designed to
differentiate between the (A) and (B) definitions of "impedance" in
"The IEEE Dictionary". Calling the V/I (B) definition of impedance,
"virtual", is much more descriptive than calling it "the (B)
definition".

Walt is arguing that the impedance of an RF source is "non-
dissipative". Ratios of V/I are non-dissipative if they exist devoid
of an impedor. Walt adopted the word "virtual" from the optics
"virtual image". It is an image that is not really there in reality. A
virtual impedance would therefore be the image of an impedor that is
not really there.

I'm not hung up on the word "virtual". What adjective would you use to
differentiate between a dissipative impedor and a V/I non-dissipative
impedance? I am not trying to be difficult - just trying to
communicate. I'm willing to adopt any convention that you suggest for
the duration of this discussion.

I'll just quote the following from Chapter 24-11 of REFERENCE DATA FOR RADIO ENGINEERS, 1975 Edition:

QUOTE
A load of 0.4-j2000 ohms is fed through a length of RG-218/U cable at a frequency of 2.0 MHz. What are the input impedance and efficiency for a 24-foot length and a 124-foot length?

(Omitting the number crunching shown...)

Tabulating the results,

Input
Length Impedance Efficiency Loss
(feet) (ohms) (%) (dB)

24 0.106-j95 1.1 19.6
124 1.8+j55 0.03 35

The considerably greater loss for 124 feet compared with 24 feet is because the transmission passes through a current maximum, where the loss per unit length is much higher than at the current minimum.
END QUOTE

As the input Z for each of these lengths is not the same as their 0.4-j2000 ohm termination, this shows the dependence of the performance of such systems on the electrical lengths of the transmission line in use.

I realize we have strayed into the real world here, because RG-218/U transmission line is not lossless even when perfectly matched at both ends.

In answer to the question you directly asked, yes. But that says nothing of whether such a transmitter, in the general case, is well represented by a Thevenin equivalent circuit with Zeq=50+j0.

As you know, there is a proposition that a transmitter "designed/adjusted for, and expecting a 50 + j 0 ohm load" can be well represented by a Thevenin equivalent circuit and naturally has Zeq=50+j0. However, that proposition is easily proven wrong by valid experiments in the real world, and those of us who have done such experiments are disinclined to accept the proposition.

>

> you expect the reason for that to be related to "reflected power?"

Average power at the transmitter terminals is given by the average value of the instantaneous product of v and i over time. There is no need for "net" in the calculation. The average power delivered by the transmitter will depend on the load impedance (ie the complex ratio of v/i) at its load terminals, but that dependence is not well predicted in the general case by a Thevenin equivalent circuit.

I gave a link to a simple experiment to test Zeq of a tx, and that uses equipment found in most ham shacks. The article is at http://vk1od.net/blog/?p=1028 .

The author acknowledges that loss under standing waves is not uniform, that in this case, it is higher in the region of a current maximum. That is simply explained the I^R effects on the conductors (which account for most of the loss in most practical coax cables at that frequency).

If you treated the forward and reflected waves as travelling independently, and each attenuated by the matched line loss characteristic of the line, you would get a different (and incorrect) result. It happens that we sometimes make that approximation, and under many practical scenarious, it gives a result with acceptable error, it is nevertheless less accurate because the model is poorer.

Yes, it does, and not simply on the VSWR as often inferred.

But that does not change the transmitter's behaviour in its output power being sensitive the the impedance at its load terminals, however that impedance is derived, and your response has not answered Roy's question, well at least in my mind.

>

Indeed, under some circumstances, the line can have less loss when not perfectly matched. Yes, throw those treasured graphs of ExtraLoss vs VSWR away, they depend on assumptions not usually stated.

Cases similar to the example you quoted can be solved using TLLC at http://www.vk1od.net/calc/tl/tllc.php . An interesting case is to explore the loss in 1m of RG58C/U at 3.6MHz with 50+j0, 500+j0, and 5+j0 loads. The latter two are VSWR=10, but have quite different loss. The first two cases demonstrate that VSWR does not necessarily cause extra loss (compared to the matched line case).

Yes it is OK I am not saying your article use 1/4, In a previous post
I said with 1/8 lambda TL, results support your idea of Pref
dissipating on Rs (is correct my interpretation of your idea?).
Yesterdey I posted results calculated for a 1/4 lambda TL to comparing
both ponting to 1/4 lambda results did not agree with a Pref
dissipating on RS.
Then, I thought you are not intending generalize the very common
notion of.Pref returnig to generator but seem to me you are
hypothesizing there are different mechanisms dealing with Pref
depending of the line length. Is It OK?

(Meanwhile I will take a look at the new thread to look if I can find
exactly what is the heart of this question ;>))

what is an 'impedor' in this context? that is a relatively rarely
used term in circuit and wave analysis, but is generically defined as
anything that has an impedance. that doesn't seem to fit your
definition though if you can qualify an impedance as non-dissipative
if they don't have one.

the ieee dictionary qualifiers of dissipative and non-dissipative seem
adequate to me. no need to make up any other terms or qualifiers.

Hopefully, the same IEEE Dictionary definition as any other context:
"impedor - a device, the purpose of which is to introduce impedance
into an electric circuit." Note that it has a material existence.

> the ieee dictionary qualifiers of dissipative and non-dissipative seem
> adequate to me. no need to make up any other terms or qualifiers.

OK, I will change "virtual impedance" to "non-dissipative impedance"
although if the resistance is zero, that still doesn't solve the
semantic problem. The word "virtual" as used by Walter Maxwell over
the past half-century conveys the meaning as well as any other words,
IMO.

The fact remains that a dissipative impedor is something that exists
in the material world and can cause an outcome. A non-dissipative
impedance is a *result* of a superposed V/I ratio, not a cause of
anything.

Roy once challenged me to detect the difference between a 50 ohm
antenna and a 50 ohm dummy load. I said, "Simple, use a field strength
meter."

Yes, a 1/8WL line is a *SPECIAL CASE* where zero interference exists.
In the power density equation:

Ptot = P1 + P2 + 2*SQRT(P1*P2)*cos(A)

if A = 90, then cos(A) = 0 and there is no interference term and no
interference. When you go to a 1/4WL line, it is no longer a special
case where cos(A)=0 and I have not published anything on my web page
about that condition.

Hello, here we are...! :>)

At the risk of naïve and conciliatory I still thinking that to some
extent this is a problem of "same cat seen from different points of
view".

What if the question is formulated in terms apart, for example =>
generator responses to load differences, and by what mechanism a
transmission line transforms impedances to presents to the generator
those different loads?
In that formulation I think there are room to simple, basic, and
understandable electrical laws to account for generator behaviour and
TL travelling waves interference phenomenom to account for Z
transformings.

From my perspective your main differences are reducible

wrote:

>you can qualify an impedance as non-dissipative

It's called reactance.

There are certainly some contortions that have evolved from an
argument that the source lacks the ability to dissipate.

Impedance = (R ï¿½ jX) Ohm

This is well known by all and yet it seems unsatisfactory and
impossible to measure in a Tube even when R is exhibited both by
measurement and by heat - something that by all normal accounts is
evidence of dissipation. That same heat seems to be unaccountable
because it's non-linear? If you use this heat on an ice cube, do you
get harmonics? Even or odd?

If it doesn't dissipate it must be because it has NOhms. If we embark
further on this mysterious Load Conjugation with a loss-less resistor,
what would we see for the Load Objurgation formula?

rraaZ = (Rr ï¿½ iR ï¿½ jX) NOhm

We must now have a Nimpedance measured along a second (hither too
unreported) imaginary axis. I can imagine the dawn of the new Photon
Ninterferences that will emerge from this.

Using the same transmitter originally "designed/adjusted
for, and expecting a 50 + j 0 ohm load"?

I don't suppose this anecdote has any data behind it, does it?

The easy proof has yet to wrong Walt's proposition - or did he state
something to the contrary my reading that he represented a Thevenin
equivalent circuit in the first two steps of his recent report?

I have performed many tests on many radios. One documented example is at
http://vk1od.net/blog/?p=1045 .

The concept is dealt with in more depth at http://vk1od.net/blog/?p=1028
.

Thing is that those supporting the Zeq=50 proposition, declare that since
the test showed that Zeq (or Zs in the article) is not approximately 50
+j0, then the radio isn't "designed/adjusted for, and expecting a 50 + j
0 ohm load".

Thing is that you cannot use the measured VSWR to reasonably predict the
reduction in power output (Mismatch Loss) on many HF ham radio
transceivers.

I invite you and others to perform the same test. You will realise that
one, or even 100 supporting tests do not prove the proposition, but one
valid test to the contrary is damaging.

Owen

not always. there is a non-dissipative resistance. a lossless
transmission line has a pure real impedance, but no dissipation.

define "mismatch loss".

and why would you expect that vswr is a good predictor of power
output? other than radios that use vswr sensing circuits to reduce
power output to protect their output transistors?

and why would anyone expect the output of an rf amplifier to be linear
except in a narrow range of selected loads and tuning conditions?
thats just plain crazy!

Mismatch loss is the reduction in power available in a mismatched load
compared to a matched load. Mismatch Loss can be calculated in linear
systems with Zs purely real as 1-rho^2. I wrote some notes at
http://vk1od.net/blog/?p=659 which discusses the underlying assumptions.

>
> and why would you expect that vswr is a good predictor of power

The concept of Mismatch Loss is a sound one, but application to a typical
ham transmitter is flawed because the underlying assumptions are violated
.

sure, if you properly apply the telegrapher's equations and the
thevenin equivalent methods. The real problem is that if you try to
do that for most amateur radio transmitters the source impedance is
not linear, and even worse may be time varying, which renders the
thevenin equivalent source substitution invalid.

Note though that in real world cases you need to use the full set of
equations, usually called by engineers the 'general transmission line
equations'. beware, some places may over simplify the telegrapher's
equations which may make them invalid in some cases. The
Telegrapher's equations (http://en.wikipedia.org/wiki/Telegrapher
%27s_equations), are often considered a subset of the 'General
transmission line equations (http://en.wikipedia.org/wiki/
Transmission_line) that are taught in distributed circuits and fields
and waves courses in engineering schools.

rather than worrying about basic physics, the real problem here is
that analysis of a non-linear circuit is being attempted using
techniques that are only valid for linear circuits.

2375. Radials: Induced currents due to direction versus radiation pattern

Newsgroup: rec.radio.amateur.antenna
Date: 2010-06-12 12:57:02 UTC
From: David <nospam@nospam>
Message-ID: <p8WdnXAdfpeAGY7RnZ2dnUVZ8iOdnZ2d@bt.com>
Source record: 9075

Antenna is a quarterwave vertical with quarterwave radials.

There is a difference in operation between transmit and receive modes.

In receive mode, an incident plane wave is exciting the radials. The induced currents are a function of angle around the antenna. A system of radials imperfectly reflects the incident wave, and the reflected wave is hard to calculate.

In transmit mode, the antenna base is driven by the source. The currents in the radial system are symmetrical around the antenna, NOT a function of angle, so they produce no net radiation, but do affect the input impedance.

In receive mode, the current induced in each radial is related to the direction of the incoming wave. For example, radials closest to the incoming wave experience the strongest field.

Does the radiation pattern override the direction of the incoming wave? The radiation pattern is omnidirectional or circular.

I suspect that the radiation pattern takes the incoming wave and spreads it evenly around the antenna, forming an electromagnetic field that is the same as the radiation pattern.

Even if parts of the antenna experience the strongest field due to the direction of the incoming wave, the radiation pattern means that the field is symmetrical. Is this correct?

A uniform radiation pattern means that the electromagnetic field is spread evenly around the antenna irrespective of which direction the wave is being received. Is this true?

Miguel, I don't think there is much disagreement about things that are easily measured, like voltage and current. One solution to the telegrapher's equations involves forward and reflected waves of voltage and current. The conventional way of handling power (energy/unit-time) is to use the voltages and currents to calculate the power at certain points of interest. The telegrapher's equations do not tell us *why* the power is what it is and the energy is where it is. To obtain the why, one must study the behavior of electromagnetic waves. How does the energy in electromagnetic waves behave? The telegrapher's equations and Thevenin source do not answer that question.

For instance: Most readers here seem to think that the only phenomenon that can cause a reversal of direction of energy flow in a transmission line is a simple EM wave reflection based on the reflection model. When they cannot explain what is happening using that model, they throw up their hands and utter crap like, "Reflected wave energy doesn't slosh back and forth between the load and the source". But not only does it "slosh back and forth", it sloshes back and forth at the speed of light in the medium because nothing else is possible.

These are the people who have allowed their math models to become their religion. They will not change their minds even when accepted technical facts are presented. One response was, "Gobblydegook". (sic)

There is another phenomenon, besides a simple reflection, that causes reflected energy to be redistributed back toward the load and that is wave cancellation involving two wavefronts. If the two wavefronts are equal in magnitude and opposite in phase, total wave cancellation is the result which, in a transmission line, redistributes the wave energy in the only other direction possible which is, surprise, the opposite direction. This is a well known, well understood, mathematically predictable phenomenon that happens all the time in the field of optics, e.g. at the surface of non-reflective glass. It also happens all the time in RF transmission lines when a Z0-match is

achieved.

Using the s-parameter equations (phasor math) at a Z0-match point in a transmission line:

b1 = s11*a1 + s12*a2 = 0 = reflected voltage toward the source
Square this equation to get the reflected power toward the source.

These are the two wavefronts that undergo total wave cancellation, i.e. total destructive interference.

b2 = s21*a1 + s22*a2 = forward voltage toward the load
s22*a2 is the re-reflection. Square this equation to get the forward power toward the load.

If one squares both of those equations, one can observe the interference terms which indicate why and where the energy goes. All of the energy in s11*a1 and s12*a2 reverses direction at the Z0-match and flows back toward the load. All the things that Roy is confused about in his food-for-thought article on forward and reflected power are easily explained by the power density equation (or by squaring the s-parameter equations).

Ptot = P1 + P2 + 2*SQRT(P1*P2)*cos(A)

2377. "Non-dissipative Source Resistance"

Newsgroup: rec.radio.amateur.antenna
Date: 2010-06-12 13:13:15 UTC
From: Richard Fry <rfry@adams.net>
Message-ID: <3b9c7466-5bb5-46a7-a924-8897432a5365@j4g2000yqh.googlegroups.com>
Source record: 9077

It has been theorized that a circuit consisting of a Class C vacuum-tube r-f amplifier using a tuned tank circuit in its output network provides an operational “non-dissipative source resistance” of 50 ohms for energy present at the output connector of the transmitter.

However the information and measured data provided in the text excerpts below is not very supportive of that theory.

These excerpts discuss and show the effects of the energy entering a transmitter at its output connector by frequencies offset from the transmitter frequency.

There is direct applicability of the conclusions of the paper showing that the operational source impedance of the transmitter near/at the carrier frequency is much different than 50 ohms.

If it WAS a functional 50 ohms, then the termination provided to the transmission line for signals entering the transmitter by its output connector (whether on or off frequency) would not be present at the plate of the PA tube to react with the power being generated by the PA tube.

Rather the data leads to a logical conclusion that the operational source impedance of this configuration at the carrier frequency will be very low (approaching zero), when it is optimally tuned/adjusted to produce its rated output power.

Further discussion or comment is invited.

RF

From:

A STUDY OF RF INTERMODULATION BETWEEN FM BROADCAST TRANSMITTERS SHARING FILTERPLEXED OR CO-LOCATED ANTENNA SYSTEMS, by Geoffrey N. Mendenhall, P.E.*

II. INTERMODULATION AS A FUNCTION OF "TURN-AROUND-LOSS".
"Turn-Around-Loss" or "Mixing Loss" describes the phenomenon whereby the interfering signal mixes with the fundamental and its harmonics within the non-linear output device. This mixing occurs with a net conversion loss, hence the term "Turn-Around-Loss" has become widely used to quantify the ratio of the interfering level to the resulting IM level. A "Turn-Around-Loss" of 10dB means that the IM product fed back to the antenna system will be 10dB below the interfering signal fed into the transmitter's output stage.

"Turn-Around-Loss" will increase if the interfering signal falls outside the passband of the transmitter's output circuit, varying with the frequency separation of the desired signal and the interfering signal. This is because the interfering signal is first attenuated by the selectivity going into the non-linear device and then the IM product is further attenuated as it comes back out through the frequency selective circuit.

"Turn-Around-Loss" can actually be broken down into the sum of three individual parts:
(1) The basic in-band conversion loss of the non-linear device.
(2) The attenuation of the out-of-band interfering signal due to the selectivity of the output stage.
(3) The attenuation of the resulting out-of-band IM products due to the selectivity of the output stage.

Of course, as the "Turn-Around-Loss" increases, the level of undesirable intermodulation products is reduced and the amount of isolation required between transmitters is also reduced.

The small portion of the interfering signal that is not reflected is what causes intermodulation products to be generated. Obviously the lower the output source impedance, the more complete the reflection (lower return loss), with the result being less production of intermodulation products.

III. EQUIPMENT PARAMETERS THAT AFFECT INTERMODULATION LEVELS.
The interfering signal must be coupled into the transmitter's output stage before the IM products are produced and the output level of the intermodulation products will be related to the interfering signal level.

The two parameters (outside of the filterplexing equipment) that most affect the interfering signal level into the transmitter's output circuit are the output loading and the circuit's frequency selectivity (loaded "Q"). These two parameters are interrelated because the degree of output loading will change the loaded "Q" of the output circuit while also affecting the return loss of the interfering signal looking into the output circuit.

"Output Return Loss" is a measure of the amount of interfering signal that is coupled into the output circuit versus the amount that is reflected back from the output circuit without interacting with the non linear device.

To understand this concept more clearly, we must remember that although the output circuit of the transmitter is designed to work into a fifty ohm load, the output source impedance of the transmitter is not fifty ohms. If the source impedance were equal to the fifty ohm transmission line impedance, half of the transmitter's output power would be dissipated in its internal output source impedance. The transmitter's output source impedance must be low compared to the load impedance in order to achieve good efficiency.

The transmitter therefore looks like a voltage source driving a fifty ohm resistive load. While the transmission line is correctly terminated looking toward the antenna (high return loss), THE TRANSMISSION LINE IS GREATLY MISMATCHED LOOKING TOWARD THE OUTPUT CIRCUIT OF THE TRANSMITTER (LOW RETURN LOSS). THIS MEANS THAT POWER COMING OUT OF THE TRANSMITTER IS COMPLETELY ABSORBED BY THE LOAD WHILE INTERFERING SIGNALS FED INTO THE TRANSMITTER ARE ALMOST COMPLETELY REFLECTED BY THE OUTPUT CIRCUIT.

VI. CONCLUSIONS

1. "Turn-Around-Loss" is a function of the particular non-linear device and the amount of loading on its output circuit.
2. "Turn-Around-Loss" increases as the interfering signal and the resulting IM products are moved away from the carrier and out of the output circuit passband.
3. "Turn-Around-Loss" will be least when the interfering signal is within the transmitter's passband.

The figure posted at the link below shows the measured data supplied with this paper.

Well, that's certainly one problem but I was talking about linear circuit analysis. When will the effects of linear wave cancellation be understood by the ham radio community?

Walt seems to have sidestepped the non-linear source problem by defining the "source" as the first point in the system at which the source signal becomes linear after filtering. He seems to draw a system box boundary through that point and labels that signal, "the source". The ratio of voltage to current at that point is, by definition, the source impedance. That approach sure does simplify things.

The output of a class-C amp is weighted with odd harmonics. The system is obviously mismatched at the odd harmonic frequencies.

they won't because waves don't 'cancel' any more than they 'interact' in linear systems. they do superimpose which gives the illusion of cancellation and intensification. the worst thing causing amateurs problems is using power and trying to think about energy... neither one is a linear phenomenon, but they are often treated as such because of some simple cases where you can add and subtract powers... when someone who doesn't understand the restrictions fully tries to use powers on more general cases they get in trouble. that is why it is always better to use current or voltage where you can (in many more cases) add them linearly and be correct. of course then there are those who try to push even those restrictions back into non-linear realms, like amplifiers, and get into even more trouble.

yeah, lots of words that say things kind of related, but more
confusing than useful for what is really being discussed.

what is so hard about stating:
1. tubes and transistors are non-linear devices
2. tank circuits and other output matching systems TRY to make them
appear more linear to the outside world, but are not perfect.

any circuit that has non-linear characteristics will have a response
that is not like a simple resistance. such systems must be modeled
using appropriate non-linear techniques to get the full and proper
response characteristics. An APPROXIMATION may be used in many
systems that allows an equivalent simple impedance representation, but
often only over SMALL ranges of voltage/current or frequency. The
problem appears to be in this discussion that some people have used
this small signal approximation to derive results in a domain where it
is not applicable and are drawing the wrong conclusions.

Here's proof otherwise:

b1 = s11*a1 + s12*a2 = 0 = reflected voltage toward the source

The permanent result is that reflected voltage and power equal zero?
How can that possibly be an illusion?

(b1)^2 = (s11*a1 + s12*a2)^2 = 0 = reflected power toward the source.
s11*a1 is not zero, s12*a2 is not zero, they are equal in magnitude
and opposite in phase.

What happens to the non-zero (s11*a1 + s12*a2)^2 power? The answer to
that question is what a lot of people are missing.

Those two reflected wavefronts have interacted destructively and
canceled. That destructive interference energy is redistributed back
toward the load as constructive interference energy in the other s-
parameter equation.

b2 = s21*a1 + s22*a2 = forward voltage toward the load

(b2)^2 = (s21*a1 + s22*a2)^2 = forward power toward the load

Doesn't the fact that reflected energy cannot be traced using only the
wave reflection model indicate that there is something missing from
that procedure?

Hello Richard Fry,

First, I use your last name also to avoid confusion with Richard
Clark.

As you may know, I have also doubts about the conjugated match issue.
So I am happy with this posting. It is not that I dispute the
conjugated match condition itself, but whether or not the conditions
are met. In my opinion, required conditions aren't met in many cases,
so output impedance of many amplifiers is not equal to the load
resistor.

To avoid discussions about measurements and traceable measurement
instruments/procedures, I did some simulations on a valve amplifier
and a class C mosfet circuit (that actually isn't operating in class C
mode). Everyone can do these simulations at their own PC en get an
opinion. I also described the difference frequency method that is
easily implemented in simulation and gives the output VSWR almost
directly without complex calculus. The link is: www.tetech.nl/divers/PA_impedance.pdf.

Except for the condition of matching to maximum power output given
certain drive, all output VSWR of the amplifiers is far from expected
load impedance. Just a little voltage saturation (for example to get
better efficiency) did drop the plate impedance below the required
load impedance (voltage source behavior). When reducing the drive, the
plate impedance rises rapidly above the load impedance (current source
behavior).

So power entering the output of the amplifier will mostly be reflected
back into the cable, unless you specially design for output impedance.
I know, this is disputed by some members of this group, but therefore
I did the simulations and presented the results.

I specially took "amateur" examples to avoid comment that I only use
"exotic" examples. I did not copy results from professional

activities, so I will not run into problems. The circuits are simple to ease reproduction in any spice based simulator.

I dispute:
"If the source impedance were equal to
the fifty ohm transmission line impedance, half of the transmitter's output power would be dissipated in its internal output source impedance."

A real class C amplifier with very small conduction angle has efficiency > 50% when optimally tuned. When it operates at the transition of current/voltage saturation is can show 50 Ohms output impedance for very small change in load impedance. But as soon as the load mismatch is above about VSWR = 1.05…1.1, output VSWR/impedance of the amplifier changes rapidly. So practically spoken, most high efficient amplifiers have high output VSWR (or bad Return Loss), but theoretically it can be 50 Ohms (for example). If there are doubts I will add a special simulation example for this.

Best regards,

Wim
PA3DJS

For some additional input -- I have taken part in factory tests of
high-power Class C single-tube/tuned cavity FM broadcast transmitters
driving 50-ohm test loads measured to have < 1.03VSWR, showing a DC
input to r-f output efficiency of the PA to be in excess of 80% --
including the loss in the harmonic filter. Load power was measured
using calorimetric methods. In fact, 80% PA efficiency is the
published spec for this transmitter line as long as load VSWR relative
to 50 ohms is 1.7:1 or less (any phase angle).

Those results don't appear to be fitting very well with the idea that
the tx source impedance can be ~50 ohms for loads with low VSWR.

No, not at all. It is important to realize that a real source is NOT necessarily like either the Thevenin or the Norton equivalent. The Thevenin and Norton equivalents, when discussed in any respectable text, will be noted to behave exactly like any other real linear source with respect to the load, but NOT necessarily with respect to the source itself, and in particular with respect to source efficiency and dissipation.

For example: I can, at least theoretically, build a switching power supply (a source) which measures its output voltage and current and adjusts the voltage down by 50 volts for each amp that's drawn from it. Because it is always operating as a switching supply with very high efficiency, even when it's loaded so the output voltage is half the zero-current output voltage, it's not behaving internally like a Thevenin equivalent, even though it has a 50 ohm output resistance.

As Wim says, the conjugate-matched output impedance is guaranteed only over a very narrow range of conditions. Specifically, it's for the condition where you can't adjust the load impedance in any direction without lowering the power delivered to the load. For a power output stage with a tank that can tune both resistance and reactance (such as a pi network), that should be equivalent to adjusting the pi network to maximize the power delivered to the load with a particular fixed set of bias/drive conditions for that output stage.

But why would I necessarily want to operate the output stage that way? What if I'm providing enough grid drive and plate voltage to my 6146 that it's capable of outputting 150 watts (class C), but if I were to tune up the output matching network to get that much output power, the tube's life would be significantly shortened because the plate dissipation would be too high? What if I'm operating it class AB, with low enough drive so that the plate voltage and current change only by small percentages?

Or to me, more to the point: why would I care what the source impedance of my transmitter is? With the power at the wall outlet in my house, I expect a nearly constant voltage, and have no intention of loading it with a "conjugate match." I don't know WHAT its source resistance is, exactly, but I know it's much lower than the loads I put on it. With an electric motor, I have no intention of putting a load in excess of the motor's rating on it, for fear of burning up the motor, even though I know that for short periods the motor can deliver quite a bit more output power than its nameplate rating. With a switching power supply, same thing: I don't load it to the point of significant drop in output voltage. All I want from ANY of these, including the RF power amplifier, is the ability to deliver the expected power to the rated load.

In the instrumentation systems I deal with professionally, there are times I care very much about source impedance. With respect to ham transmitters and power amplifiers, though, I just can't get excited about caring that much what the source impedance is. The point of the amplifier or transmitter is to deliver power to my antenna system, and the source impedance it represents is irrelevant to that task.

Cheers,
Tom

>
>>there is a proposition that a transmitter "designed/adjusted
>>for, and expecting a 50 + j 0 ohm load" can be well represented by a
>>Thevenin equivalent circuit and naturally has Zeq=50+j0.

On Sat, 12 Jun 2010 00:19:34 GMT, Owen Duffy <none@no.where> wrote:

For the data I asked, you supplied:
>I have performed many tests on many radios. One documented example is at
>http://vk1od.net/blog/?p=1045 .
and offered:
>I invite you and others to perform the same test. You will realise that
>one, or even 100 supporting tests do not prove the proposition, but one
>valid test to the contrary is damaging.

The test of proving the "proposition" invalid is, in part:
>Adjusting the load impedance ... on this load with VSWR(50)=1.5
>... is proof that the equivalent source impedance of the transmitter is not 50+j0Ohm.

I observed how you violated the adjusted-for part of
"designed/adjusted for, and expecting a 50 + j 0 ohm load."

As no claim has been made by anyone about a source being constant in Z
nor in Power across all loads and all frequencies, your response does
not conform to your own reprise of the "proposition."

****

What you have performed is a load pull which constructs a curve of
complex source impedances around the point at which the transmitter
was adjusted for a 50 Ohm load. All well and good. However,
Thevenin's theorem says nothing of this. The correct test, to the
letter of the theorem is a test no one performs: the measured open
circuit voltage divided by the measured short circuit current.

****

If I were to return to another statement from your link offered in my
quote above:
>the transmitter is 50+j0Ohm
is in all likelihood incorrect. I am speaking strictly to what is
reported and to the implied accuracy of 50 ï¿½0.5 Ohms. I seriously
doubt that you have the means to achieve the absolute accuracy of 1%.

To many, this is a trivial point - simply because they, too, are wholly incapable of achieving even ten times this error. That is, measure an RF power in the HF to within ï¿½10%. So I often get shrugged off with a dismissal of "so what?"

What is this scrabbling over decimal points that I am making? IF:
>the equivalent source impedance of the transmitter is not 50+j0Ohms
then it could easily be satisfied by it being 51+j0Ohms, as you do not report what the Z was. I am sure some would condemn 51 Ohms with sneering contempt. Reports of what the Source Z "is not" is not informative in the least. What the significance 1 Ohm has when the likelihood of being able make a measurement with much less range of error is approaching nil and thus does not stand as a very rigorous proof AGAINST the "proposition."

Similarly, IF:
>the equivalent source impedance of the transmitter is 50+j0Ohms
then even this may not qualify if the source impedance MUST be 50+j0Ohms as, again, the likelihood of being able make a measurement within ï¿½1% range of error is approaching nil and thus does not stand as a very rigorous proof FOR the "proposition."

****

Last, I see the lack of rigor in reporting that is so evidenced by Walt's work. I am familiar with EVERY one of his lab instruments (enumerated elsewhere) as I have calibrated ALL like them in three different RF Standards laboratories over my career as a Metrologist. I am wholly informed as to their capabilities and capacities to perform the tests he reports to the precision and accuracies he documents. I am also trained in the methods of performing this work and I have read from Walt's descriptions that he has taken care to observe the proper methods. All of these considerations are scrupulous to his first two steps of his description which amply demonstrate:
>>there is a proposition that a transmitter "designed/adjusted
>>for, and expecting a 50 + j 0 ohm load" can be well represented by a
>>Thevenin equivalent circuit and naturally has Zeq=50+j0.

that assumes the source is linear... with a non-linear source it is
much more complicated to describe the full range of it's response.
you would have to do a series of output voltage vs current curves for
a range of impedances.

Hi David,

Ah! The appeal of the infinite, lossless transmission line. You
forgot radiation.

I think we can both agree that it can be measured, even by the
inference of a chain of measurements and those measurements would
consistently show the absence of heat.

I think you would enjoy the absurdity of its appeal to being the plate
"resistance" when the 1400 Ohms there would be embodied in 28
infinitely long lossless cables being tucked inside the tube.

For others,

If it were so (where those 28 infinitely long lines are tucked into
another convenient dimension that sprang into being to satisfy
argument), then what is the source of the heat of the plate that is in
excess of that of the DC operating point?

If some feel compelled to jump on the losslessness of radiation loss
(now, if that isn't a paradox) - all fine and well for Art's short
wound self-resonant radiators that would eventually devolve in size to
the plate tank. If plate resistance was due to radiation, what need
for antennas? Of course, we could add another rhetorical dimension
that absorbs radiation....

Hello Richard Fry,

I quote a sentence from your previous post:

"Would that not be evidence that the amplifier source impedance necessarily is lower than the load impedance?"

What you have said above is the key to the concern over the output resistance of a Clsss C amplifier being non-dissipative. What seems to be universally misunderstood is that there are really two separate resistances in the operation of these amps; one, the cathode-to-plate resistance, which is the dissipative resistance Rpd that accounts for all the heat, due to the electrons striking the plate; and two, the real output resistance that appears at the output of the pi-network, the resistance comprised of the voltage-current ratio E/R. I am speaking only of tube amps using an adjustable pi-network in the output. Due to the energy storage in the pi-network the output of the amp is inherently isolated from the upstream non-linear portion, thus the output is linear. One of the myths concerning the RF amp is that it cannot have efficiency greater than 50% because half of the power is dissipated in the source resistance. This would be correct if the output source resistance was dissipative, like in a classical generator. But in the real RF xmtr this is not true.

Returning now to your quote above, your reference to the source impedance (resistance Rpd) is actually the plate-to-cathode resistance, the dissipative resistance, which is less than the output resistance R = E/I appearing at the terminals of the pi-network. I must add that when the pi-network has been adjusted to deliver all the available power at any particular grid-drive level, the output resistance of the network equals the load resistance, but not necessarily 50 ohms, i.e., whatever the load resistance might be.

If you have doubts concerning the conditions I stated above, I invite you to review Chapter 19 in Reflections 3, which is available in two parts on my web page at www.w2du.com, as the first part appears in Reflections 2 and the second part appears in 'Preview of Chapters in Reflections 3'. In that chapter I use an example taken directly from Terman's 'Radio Engineers Handbook'. You will note that the dissipative resistance Rpd (3315.6 ohms) is less than the output resistance (6405 ohms) obtained from the E/I relationship appearing at the output

This example verifies the explanation in the text. In addition, I also invite you to review the portion of the chapter appearing in the 'Preview Chapters in Reflections 3', in which I report additional measurements that offer additional proof that the output source resistance is non-dissipative. The numbers prove it to be true.

K1TTT is correct--the transmit and receive modes are reciprocally
related, and thus are identical in operation. The vertical radiator is
non-directional, and is the receptor in the receiving mode. The
radials are not receptors and are not involved the directivity on
reception.

The IC7000 has no relevant user adjustments, it is designed for and
adjusted for in its design, manufacture, and alignment.

>
> As no claim has been made by anyone about a source being constant in Z
> nor in Power across all loads and all frequencies, your response does
> not conform to your own reprise of the "proposition."

To be usable, any pretence of linearity at least over a limited range of
loads, power, frequency, Zeq must be sufficiently constant within that
range.

> What you have performed is a load pull which constructs a curve of
> complex source impedances around the point at which the transmitter
> was adjusted for a 50 Ohm load. All well and good. However,

No, I have performed a go/nogo test on whether the transmitter delivers
sufficiently constant forward power into a quite limited range of loads.
The meaning of "sufficiently" is proposed in the reference article
describing the test and providing the mathematical basis for the test.

> Thevenin's theorem says nothing of this. The correct test, to the
> letter of the theorem is a test no one performs: the measured open
> circuit voltage divided by the measured short circuit current.

No, Thevenin's theorem does not speak at all of how to test a source. For
a linear source, your proposed test of o/c voltage and s/c current would
provide sufficient data, as would ANY two points on the (complex) v/i
relationship.

I expect that a typical HF ham transmitter output is not linear over the
entire v/i characteristic, but my test just focuses on whether it is
approximately linear over a limited range of loads.

My recollection of Walt's tests were that they tested at points other
than Zl=0 and Zl=infinity.

You dwell at some further length on the implicit accuracy of the stated quantity, but ignore the explicit discussion about a reasonable tolerance for the test.

Thevenin's theorem says nothing of what happens inside the source (eg dissipation), or how the source may be implemented.

It is the implementation of the source that provides the answer to your question, and the word "never" is too strong for the general case.

In respect of typical HF ham transmitters, you may find my article entitled "Does SWR damage HF ham transmitters?" at http://vk1od.net/blog/?p=1081 of interest.

Too bad about the "s stuff". Here are the RF equations for a Z01 to Z02 impedance discontinuity in a transmission line. The forward voltage on the Z01 side is Vfor1 and the reflected voltage from the impedance discontinuity (back toward the source) is Vref1. The forward voltage on the Z02 side is Vfor2 and the reflected voltage (from the load) is Vref2. Hopefully, the reflection and transmission coefficients are self-explanatory. rho1 is the reflection coefficient encountered by Vfor1, etc.

Vref1 = Vfor1(rho1) + Vref2(tau2) = 0

That is wavefront cancellation in action. The external reflection phasor, Vfor1(rho1), is equal in magnitude and 180 degrees out of phase with the internal reflection phasor, Vref2(tau2), arriving from the mismatched load.

Vfor2 = Vfor1(tau1) + Vref2(rho2)

If these RF equations are normalized to SQRT(Z0), they are the same as the s-parameter equations.

It is my understanding that the average power (heat) generated at the anode of a triode can be found by averaging the product of the instantaneous anode current and anode-cathode voltage over time. In a Class C amplifier, the voltage and current are not linearly related to each other, ie there is no constant of proportionality, no constant or fixed resistance.

I don't understand why then, that people try to explain the anode dissipation in terms of some value of resistance.

Richard,

The article does propose a practical tolerance. I quote the relevant paragraph below.

"Of course, nothing is perfect so an acceptable tolerance for depending on the assumed Zs=50+j0? for Mismatch Loss calculations might be that forward power doesn't vary by more than 10% of the reflected power at any point. The worst case reflected power for the experiment as described is 4%, so a variation of forward power by more than 0.4% (ie 0.4W in 100W) at any point would indicate significant error in any Mismatch calculations based on an assumed Zs=50+j0?."

I explained in the articles how I am able to reliably detect such small relative power variation. In one of the tests, the measured variation was 21%.

My intention in publishing the two articles wasn't to prove the propostion one way or the other, but to show practical amateurs a test that they could make with relatively simple equipment, one that is relevant to the application of Zs if it was known, and an explanation of why it works so that they can understand the test and make their own interpretations about significance.

Hello Owen thank you for your answer: Sorry I do not quite understand
your answer. I choose a Thevenin model of circuit theory because it is
an idealization consisting of an idealized constant voltaje source in
series with an idealized resistance without any relation with
practical implementation of such imaginary electrical (and
mathematical) entity.

I first interested get from you such idealized model answer as a
reductionistic aproximation method to try arrive later at subsequent
interpretations of practical situations. I think we all used to
working with idealized models and we accept its limitations, but we
also know frequently they are very useful to clear the "field" (as in
football "field")
(I said "never" because Cecil seem say "sometimes").
For example: ideal conjugate mirror in Maxwell article in my
interpretation implicates "never". Reflected power do not return to
the source in that context.
If you prefer I would be equally satisfied knowing who agree with
"never", who with "sometimes" and who with "always". But I would not
be too annoying :>)

I would call two waves superposing to zero indefinitely, "wave
cancellation". If that is not wave cancellation, where did the
reflected and refracted wavefronts go along with their energy
components? The answer to that question will reveal exactly what
happens to the reflected energy.

Here's a brain teaser for you and others. Given a Z01 to Z02 impedance
discontinuity with a power reflection coefficient of 0.25 at the '+'
discontinuity:

------Z01------+------Z02-------load

Pfor1 in the Z01 section is 100 watts. Pref1 in the Z01 section is
zero watts.

What is Pfor2, Pref2, and the SWR in the Z02 section?

Hi David,

In the proximity of an antenna, you do not encounter mirror-like
reflections, nor anything approaching them. I am sure you have seen
tutorials or references that give the appearance of reflection in
association with an antenna. However, if you look closely, those
reflections are in the far-field (some several to tens to hundreds...
of wavelengths away).

This reflection metaphor is generally illustrated with explanations of
ground mounted verticals. It is a useful concept that is only
observed at a great distance. In other words, for it to work the way
they show it, you can't get close enough to observe it.

Hi Richard,

Deja Vu all over again. I suppose you posted this to inspire me to,
once again, remind you from Mendenhall's own notes about Class C
amplifier construction - and so I will:

"It was thus necessary to determine the plate load impedance
= (Eb - Emin) / I1
~= Eb/ Idc
~= 1000 Ohms
[Not very far from Walt's determination of 1400 Ohms from his own
bench.]
"Since this was to be coupled into a Z output of 50 Ohms, a impedance
transformation of 20:1 was needed. This was accomplished by using a
voltage divider of two series capacitors to series tune the plate
circuit."

The tube is an EIMAC 4CX300A running no where near capacity.

All details (and more) written in Mendenhall's own hand.

Miguel,

From Wikipedia: "Th&#65533;venin's theorem for linear electrical networks states that any combination of voltage sources, current sources and resistors with two terminals is electrically equivalent to a single voltage source V and a single series resistor R. For single frequency AC systems the theorem can also be applied to general impedances, not just resistors."

The theorem does not state or imply that the Thevenin equivalent circuit dissipates the same internal power as the real source, just that any *linear* two terminal circuit containing sources and impedances can be reduced to this two component equivalent (at a single frequency), and V and I at the network terminals will be the same as the original network, irrespective of the external load attached to the network terminals.

It is a simple exercise to develop two source networks with the same Thevenin equivalent circuit, but that have quite different internal efficiencies. It is easy to demonstrate that both networks deliver the same power to any given load, but that the internal dissipation of those source networks is different in both cases, and not explainable simply as absorbing 'reflected power'.

This is basic linear circuit theory.

If there was a valid Thevenin equivalent circuit for a transmitter (and that is questionable), then you can not use that equivalent circuit to make any inference about the internal dissipation of the source (the transmitter in this case), or its efficiency. Nevertheless, I see people trying to do this one way or another in the various threads here.

I know that in this age of instant gratification, people reading posts in these fora tend to accept simple dogmatic statements as sure sign of author credibility, and qualifications such as 'often', 'usually' etc as a sign of uncertainty, of a lack of understanding, of weakness in the author. The opposite is often, if not usually true.

In English, we have a saying "never say never".

What 'never'? 'Hardly ever'... to borrow some dialogue.

A man who is hardly ever wrong doesn't use words like 'always' and 'never' much, or imply as much in general statements.

Owen

A lossless line infinite in extent is the typical definition that
corresponds to its characteristic "non-dissipative" resistance. That,
or it is terminated in a lossy resistor (and the loss is suddenly in
everone's face, full and foursquare).

How long are you going to wait to finish the energy budget to measure
IF there is missing energy from an infinite line?

Hi Owen,

Excuse me for incorrectly referencing your material as lacking in that
regard.

>I explained in the articles how I am able to reliably detect such small

But what lead us here was that you had proof, at least through some
third party (the experience of your having seen something that
diminished the "proposition"). I asked for that specifically. I have
not seen any reputable counter to Walt's data supporting the
"proposition."

The point remains that out of tolerance loads do not invalidate the
"proposition:"

In fact they announce themselves as violating the "proposition."

I hope this does not return us to the vacant adjectives, which as an English major, I can full well argue to greater advantage. I don't think that is productive, but choices remain to pursue them, or to introduce new facts.

****

Now, let's return to your paragraph, how do you know where the 50 Ohm point was? You are relying on relative accuracy to make an absolute measurement. This only works if you have a standard to make a transfer from. Walt did this but it is arguable that his 1400 Ohm resistor was, in fact, that value - however, he had the correct tools to measure it.

Your two test results could be inverted (fail/pass for pass/fail), or they could both be pass, or both fail.

I have calibrated many loads from DC to 12 GHz - and most of them failed for many and sundry reasons and had to be "qualified." In the vernacular of the standards laboratories that means a table of correction values that are valid as long as certain characteristics are met. I prepared many such lengthy reports as no one was going to buy a new load each calibration cycle (typically 3 or 6 months).

I own one that met 1% accuracy out to 1GHz (@150W), but that was luck of the draw and I wouldn't be so naive as to claim it retains that accuracy - however, experience has revealed that with care it should. Aging loads is like aging wine - there is no stasis. Here we get back into subjectives, but I know the limits of care, and I know how to practice it. If pressed to prove my inference of 1%, I also have the skill to do so to that accuracy according to methods practiced by Metrologists. It would be exceedingly tedious. Exceedingly tedious. Or I could pay for it to be done.

From Mendenhall:

"VHF amplifiers often exhibit a somewhat unusual characteristic when
tuning for maximum efficiency. ... If the amplifier is tuned exactly
to resonance, the plate load impedance will be purely resistive and
teh load line will be linear."

From "Care and Feeding of Power Grid Tubes:"

"The first step in designing the output circuit is to specify the
resonant load impedance of the tube, the loaded Q of the circuit and
the desired output impedance of the network. The resonant plate load
impedance for the 4065A is determined by dividing the plate peak RF
voltage swing by the plate peak fundamental RF current.
[work shows Resonant load impedance = 7600 Ohms]
"if it is assumed that the output impedance of the network is to be 50
Ohms, and the loaded Q is to be 15, the output tuned circuit may now
be designed. The output impedance of 50 Ohms will match into a
properly terminated 50 Ohm transmission line."

This document provides plenty of math and charts for the design of
efficient output networks (finals' plate load).

Hello Owen, good day in Australia I hope!

Sorry, with due respect, your answer throws back the ball out of the
soccer field :>)
I like poetry also but would you mind search the web for another
scientific uses of "never" word?, such as in
http://www.upscale.utoronto.ca/PVB/Harrison/Entropy/Entropy.html.

Of course many thanks for your time and your kind reply.

Miguel LU6ETJ

Hi Miguel,

Lastly first, your reference uses "never" in the statement of a law of physics. That might be a safer place to use it than your typical ham assertions like "a non-resonant antenna is never going to work as good as a resonant one".

I am not sure what "throws the ball out of field". Is it the misuse of Thevenin equivalent circuits?

I tempted you to an exercise. In case you didn't try it, try this one.

I have three ideal components, a 1000V voltage generator, a 999.5 ohm resistor, and a 1 ohm resistor, all in series. They are in a black box, and both ends of the 1 ohm resistor are bought out to two terminals on the black box. It is a trivial exercise to show that load that will develop the most power is approximately 1 ohms. At that point, the load voltage is 0.5V, and load power is 0.25W. Efficiency of the system (ie Pout/Pin) is 0.25/1000=0.025%. The o/c voltage is approximately 1V and internal dissipation is approximately 1000W, the s/c current is approximately 1A and internal dissipation is approximately 1000W.

I have another black box with a 1.0005V generator and a series resistance of 0.999000 ohms bought out to its two terminals. It produces exactly the same o/c current, but with internal dissipation of 0W, exactly the same s/c current with internal dissipation of approximately 1W, maximum power of approximately 0.25W in an approximately 1 ohm load for system efficiency of 50%.

Both of these networks have the same Thevenin equivalent circuit (in fact one is the equivalent circuit), they produce the same load current, load power, load voltage on the same load impedance, but their internal dissipation and efficiency is quite different.

The Thevenin equivalent circuit cannot be used to explain the internal dissipation or efficiency of a source network, but it can be used the explain the behaviour of the load network.

Owen

Sorry I ommited one comment:
The final Thevenin circuit is an idealization built with an ideal
voltage source in series with an ideal resistor. This new idealized
circuit It is a new born entity whose properties are now fully
described for these only two idealized circuit elements. These are the
virtues and the defects of reductionist models :>(

R. R. Well... I forget to say the more important => For the sake of
the advance of the topic please do replace "Thevenin circuit" in my
original question for "an ideal constant voltage source in series with
an ideal resistance" equivalent only to itself :>)

i don't care, i know that the superimposed voltage or current is
zero. from that i can calculate the power or energy anywhere i
want.

why does anyone care about 'energy' anyway, that is even worse to
think about in transmission lines than power. at least you can
measure, or at least calibrate your meters, in power units. have you
ever seen an amateur station that had an energy meter on their
transmitter? and isn't the term 'reflected energy' kind of an
oxymoron anyway? for energy to be reflected it has to be moving, so
isn't that just another word for power?

I seem to recall this subject was written about in Communications
Quarterly. Now QEX.
Then debated in the next few issues in the Technical Conversations section,
and then
there may have even been a second article written as debate to the first.
I thought the key term was conjugative match, but with a quick look all I
found was
a winter 1999 article more about tuners and cable "VSWR, Reflections, and
the Conjugate
Impeadance Match.
Your subject "tube r-f amplifier using a tuned tank circuit (output
impedance)" was very
hotly debated over several issues. It was all above my ability, but I
gleaned a little from it.
Someone with an ARRL membership can search the index and get the issues
with the articles
and all the technical correspondence.

"Richard Fry" <rfry@adams.net> wrote in message
news:3b9c7466-5bb5-46a7-a924-8897432a5365@j4g2000yqh.googlegroups.com...
It has been theorized that a circuit consisting of a Class C vacuum-
tube r-f amplifier using a tuned tank circuit in its output network
provides an operational "non-dissipative source resistance" of 50 ohms
for energy present at the output connector of the transmitter.

However the information and measured data provided in the text
excerpts below is not very supportive of that theory.

These excerpts discuss and show the effects of the energy entering a
transmitter at its output connector by frequencies offset from the
transmitter frequency.

There is direct applicability of the conclusions of the paper showing
that the operational source impedance of the transmitter near/at the
carrier frequency is much different than 50 ohms.

If it WAS a functional 50 ohms, then the termination provided to the
transmission line for signals entering the transmitter by its output
connector (whether on or off frequency) would not be present at the
plate of the PA tube to react with the power being generated by the PA
tube.

Rather the data leads to a logical conclusion that the operational
source impedance of this configuration at the carrier frequency will
be very low (approaching zero), when it is optimally tuned/adjusted to

produce its rated output power.

Further discussion or comment is invited.

RF

From:

A STUDY OF RF INTERMODULATION BETWEEN FM BROADCAST TRANSMITTERS SHARING FILTERPLEXED OR CO-LOCATED ANTENNA SYSTEMS, by Geoffrey N. Mendenhall, P.E.*

II. INTERMODULATION AS A FUNCTION OF "TURN-AROUND-LOSS".
"Turn-Around-Loss" or "Mixing Loss" describes the phenomenon whereby the interfering signal mixes with the fundamental and its harmonics within the non-linear output device. This mixing occurs with a net conversion loss, hence the term "Turn-Around-Loss" has become widely used to quantify the ratio of the interfering level to the resulting IM level. A "Turn-Around-Loss" of 10dB means that the IM product fed back to the antenna system will be 10dB below the interfering signal fed into the transmitter's output stage.

"Turn-Around-Loss" will increase if the interfering signal falls outside the passband of the transmitter's output circuit, varying with the frequency separation of the desired signal and the interfering signal. This is because the interfering signal is first attenuated by the selectivity going into the non-linear device and then the IM product is further attenuated as it comes back out through the frequency selective circuit.

"Turn-Around-Loss" can actually be broken down into the sum of three individual parts:
(1) The basic in-band conversion loss of the non-linear device.
(2) The attenuation of the out-of-band interfering signal due to the selectivity of the output stage.
(3) The attenuation of the resulting out-of-band IM products due to the selectivity of the output stage.

Of course, as the "Turn-Around-Loss" increases, the level of undesirable intermodulation products is reduced and the amount of isolation required between transmitters is also reduced.

The small portion of the interfering signal that is not reflected is what causes intermodulation products to be generated. Obviously the lower the output source impedance, the more complete the reflection (lower return loss), with the result being less production of intermodulation products.

III. EQUIPMENT PARAMETERS THAT AFFECT INTERMODULATION LEVELS.
The interfering signal must be coupled into the transmitter's output stage before the IM products are produced and the output level of the intermodulation products will be related to the interfering signal level.

The two parameters (outside of the filterplexing equipment) that most affect the interfering signal level into the transmitter's output circuit are the output loading and the circuit's frequency selectivity (loaded "Q"). These two parameters are interrelated because the degree of output loading will change the loaded "Q" of the output circuit while also affecting the return loss of the interfering signal looking into the output circuit.

"Output Return Loss" is a measure of the amount of interfering signal that is coupled into the output circuit versus the amount that is reflected back from the output circuit without interacting with the non linear device.

To understand this concept more clearly, we must remember that although the output circuit of the transmitter is designed to work into a fifty ohm load, the output source impedance of the transmitter is not fifty ohms. If the source impedance were equal to the fifty ohm transmission line impedance, half of the transmitter's output power would be dissipated in its internal output source impedance. The transmitter's output source impedance must be low compared to the load impedance in order to achieve good efficiency.

The transmitter therefore looks like a voltage source driving a fifty ohm resistive load. While the transmission line is correctly terminated looking toward the antenna (high return loss), THE TRANSMISSION LINE IS GREATLY MISMATCHED LOOKING TOWARD THE OUTPUT CIRCUIT OF THE TRANSMITTER (LOW RETURN LOSS). THIS MEANS THAT POWER COMING OUT OF THE TRANSMITTER IS COMPLETELY ABSORBED BY THE LOAD WHILE INTERFERING SIGNALS FED INTO THE TRANSMITTER ARE ALMOST COMPLETELY REFLECTED BY THE OUTPUT CIRCUIT.

VI. CONCLUSIONS
1. "Turn-Around-Loss" is a function of the particular non-linear device and the amount of loading on its output circuit.
2. "Turn-Around-Loss" increases as the interfering signal and the resulting IM products are moved away from the carrier and out of the output circuit passband.
3. "Turn-Around-Loss" will be least when the interfering signal is within the transmitter's passband.

The figure posted at the link below shows the measured data supplied with this paper.

http://i62.photobucket.com/albums/h85/rfry-100/TAL_Chart.gif

If you believe by your understanding of the clips you quoted from Mendenhall that a conventional, single vacuum tube Class C r-f amplifier provides a functional termination of 50+j0 ohms for energy applied to the output connector of the transmitter, then please explain why that termination allows such signals to reach the plate of the PA tube -- whose non-linear characteristics created the _measured_ r-f intermodulation products and other performance data given in the Mendenhall paper I quoted.

In his food-for-thought article on forward and reflected power, Roy
(w7el) says: "So we can model a 100 watt forward, 50 ohm nominal
transmitter as a 141.4 volt (100 * sqrt(2)) RMS voltage source in
series with a 50 ohm resistance." He goes on to calculate power
dissipation in the source resistor.

You get exactly the same answers doing it my way but my way yields the additional information of exactly what happens to the energy components. When two wavefronts superpose to zero indefinitely, I would take that as proof of interaction and wave cancellation.

This is what invariably happens to the discussion. After being told that I am absolutely wrong about energy flow, I introduce the known laws of EM physics from the field of optics and prove that they provide exactly the same answers as a conventional RF analysis. After some discussion, it is asserted that the person (not only you) doesn't care and it doesn't matter anyway. W7EL says in his food-for-thought article, "I personally don’t have a compulsion to understand where this power 'goes'."

A 1/4WL series matching stub is essentially the same function in concept as a 1/4WL thin-film coating on non-reflective glass. How the non-reflective glass works is perfectly understood and a 1/4WL series matching section works the same way. Why not glean some knowledge from the field of optics if it helps hams to understand "where the power goes"? Optical physicists were forced to track power density from the very start of their science because they didn't have the luxury of tracking the voltage and current.

The magnitudes of the voltages and currents in the above example are indeterminate. Can you (or anyone else) solve the problem without resorting to voltage and current calculations? I am just trying to get people to think outside of their rigid concrete voltage/current boxes.

hams 'know' where the power goes, their swr meter tells them it goes
back to the transmitter!

why don't physicists working in optics calculate fields? the electric
and magnetic field models work just as well at those frequencies as
they do on hf. indeed, why don't optical physicists learn something
from rf designers and model their thin films with transmission lines!

That's easy, because it *physically exists in reality* with a voltage reflection coefficient of (Z02-Z01)/(Z02+Z01) = 0.5. It is related to the indexes of refraction in the field of optics from which the same reflection coefficient can be calculated.

The difficult question is: Exactly why doesn't that same physical reflection coefficient reflect half of the forward voltage when it is Z0-matched during steady-state?

The answer is that it indeed does reflect 1/2 of the forward voltage during steady-state but that wavefront interacts with 1/2 of the reflected voltage returning from the mismatched load which is equal in magnitude and 180 degrees out of phase. In this case, superposition of the two waves results in wave cancellation (total destructive interference). The energy components in those two waves are combined and redistributed back toward the load as constructive interference in phase with the forward wave from the source. That's where the reflected energy goes.

That's why the s-parameter analysis theory could be important to hams. By merely measuring the four reflection/transmission coefficients (s11, s12, s21, s22) one learns the basics of superposition. S-parameter analysis was covered in my 1950's college textbook, "Fields and Waves in Modern Radio", by Ramo and Whinnery (c)1944. I don't know how or why the younger generation missed it.

Purposefully, the numerical values of Z01 and Z02 are not given and
unknown. The answer to the problem would be the same if Z01=50 and
Z02=150, or if Z01=100 and Z02=300, or an infinite number of other
combinations. Please tell me how you can calculate an absolute voltage
when Z0 is an unknown variable?

And a mere two sentences back one find Roy writing:
"I make no claim that the model circuit represents what's going on
inside the transmitter. For one thing, a real transmitter will
typically be more efficient than the model. However, if measurements
and observations are limited to the outside of the transmitter,
the model is very good (within the non-shutdown range). Although
a real transmitter won't contain the model's resistance as a
resistor, we will take a look at the model resistor's dissipation
to see how it interacts with the "reverse" power."

Was your disingenuity deliberate?

'Unusual'? Certainly not unexpected once one thinks about it. For a
given controlled power, the minimum dissipation in the controlling
device will occur when the minimum voltage occurs at the time of
maximum current, and vice versa, i.e. the voltage and current in the
load are in phase, or equivalently, the load impedance is resistive.

I would expect this to be a fundamental characteristic, and not just
for VHF amplifiers.

The 60Hz folk are trying to achieve the same result as they strive
for a power factor of 1.

Hello Owen,

I fully agree with you. When I am doing power electronics, I show myself the instantaneous current*voltage plot, and the averaged integral. The last one shows the dissipated power, the first one tells me where I have my losses (and also what I have to change to reduce the overall loss or reduce component stress).

Regarding the class C output impedance issue, I updated my simulations with a 3.6 MHz output stage with a 6146 tube and real class C operation.

You can almost get every impedance you want, also the conjugated match condition, but you need to do many simulations to find that point. With hours of time, I couldn’t get closer to an output VSWR of 1.58 with 79% efficiency. I know you can get closer, but at his moment I cannot provide you a spice file as I don’t have it anymore and I also dropped orcad long time ago. .

The smallest change in output loading or drive level results in significant change of output impedance. So take an arbitrary class C amplifier, measure its output impedance and it will very likely be way

off the intended load (in my example 3500 Ohm).

If you want to use load change method with some different resistive loads, you should make phase measurements to get valid results, as you don't know whether you amplifier has real or complex output impedance.

For the class C amplifier I changed the drive by +0.36 dB, resulting in an increase of plate efficiency from 79% to 80%, but the output VSWR changed from 1.58 to 3.6. Also reduction of input drive gives significant change in VSWR (magnitude and phase).

I hope that people will reproduce some of the simulation themselves to develop a solid opinion on their own.

Would you please respond in your own words directly to my
previous statement (repeated below)?

If you believe by your understanding of the clips you quoted from
Mendenhall that a conventional, single vacuum tube Class C r-f
amplifier provides a functional termination of 50+j0 ohms for energy
applied to the output connector of the transmitter, THEN PLEASE
EXPLAIN WHY THAT TERMINATION ALLOWS SUCH SIGNALS
TO REACH THE PLATE OF THE PA TUBE -- whose non-linear
characteristics created the _measured_ r-f intermodulation products
and other performance data given in the Mendenhall paper I quoted.

<keith.dysart@gmail.com> wrote:

>'Unusual'? Certainly not unexpected once one thinks about it.

Hi Keith,

The "unusual" was lost in the ellipsis that I will reveal:
"... The highest efficiency operating point does not exactly coincide
with the lowest plate current because the power output continues to
rise for a while on the inductive side of resonance coming out of the
dip in the plate current. ..."

Continuing, Mendenhall presents the problems of trade-offs between
what would seem to be maximum power for worsening characteristics in
performance - the goal is what he calls minimizing synchronous AM
versus Efficiency.

Synchronous AM is a problem that can be introduced by measurement
equipment, as Mendenhall relates: "The input impedance of the
envelope detector must provide a nearly perfect match ... 30dB return
loss ... to the sampling line."

This sidebar relates to what Owen characterized as "Usability" where I
have recited the objective technical specification to reduce the
subjectivity of the term.

There's more that could be said, but I am waiting to see if Richard is
willing to subscribe to his own reference's writings. If not, and
Mendenhall doesn't mince words on the topic, then as Perry Mason would
observe "The D.A. is impeaching his own witness!"

I've always loved Perry Mason.

>If you believe

What I believe has been succinctly laid out in my subscribing to
Mendenhall's explicit statement.

>THEN PLEASE EXPLAIN WHY

I don't see that elaboration is going to improve what has been
presented.

Yes, it is a difficult concept that many struggle with and few have
had experience in making a sufficiently accurate determination of.
Consult Walt's 333 line posting and examine how experience comes to
bear and through my recitations reveal the dovetail fit to theory.

The Only Explanation Possible:

Here's a modest proposal, Mendenhall constructed a power amplifier
that is within the technical grasp of many here to achieve at a modest
workbench. The design is quite spartan. The design is quite
understressed (there is nothing "forcing" a conclusion). The design
conforms to all engineering standards.

Build your own. [It feels strange to have to offer that option to a
group of Hams.]

Having this amplifier before you, observe all the variables, play with
them. Measure their impact on NOhms. Account for the heat with
direct measurement and note what does not conform to convention.

When that is finished the real work begins. Calibrate your tools and
repeat this for accuracy.

So your subscription to your own authority is contingent upon me?

I'm flattered.

>Also please comment on whether or not a Class C amplifier operating on
>a linear portion of its transfer curve will function as a linear
>amplifier.

"If the amplifier is tuned exactly to resonance, the plate load
impedance will be purely resistive and the load line will be linear."

I would note that the bulk of his paper concerns frequency products -
something the bears quite intimately upon linear operation.

Your question is rather opaque in that the appearance of subtext is
undoubtedly bound up in the term "linear" which Mendenhall has already
employed within the norms of amplifier design.

How linear is linear? Give me a technical criteria (subjectivity
abounds and is not very informative except for statements of fashion).
Express the least departure from a line response in percent that you
accept as being linear. If it exceeds Mendenhall's design or
commercial product, then I am afraid you won't be satisfied with any
answer.

> How linear is linear? Give me a technical criteria...

A truly linear device does not produce r-f intermodulation products when signals of different frequencies are applied to it at the same time.

For many practical uses a linear device does need to be perfectly linear. Let's say that the IM products need to be only - 20 dB w.r.t the lowest amplitude value of the various input frequencies. The Mendenhall paper I quoted conclusively shows that even such nominally linear performance is not an attribute of Class C vacuum tube r-f amplifiers -- especially at, and near the center frequency of the PA output tuning/matching network.

That Mendenhall paper also shows that such r-f amplifiers do not present a functional, 50+j0 termination to r-f energy entering via the tx output connector. That is the reason why such energy is present in the PA plate circuit, giving rise to r-f intermodulation and/or changing the power dissipation there.

Medenhall's paper shows "RF spectrum showing distortion products" that
are 30dB down.

His statement: "If the amplifier is tuned exactly to resonance, the
plate load impedance will be purely resistive and the load line will
be linear." is attached to that linearity which is greater than you
expect.

To Richard Fry,

Richard, it appears that you have ignored my post where I reported data that proves the output resistance of Class B and C RF amps is non-dissipative. Have you reviewed or ignored my reference to Chapter 19 in Reflections 3, or the combined sections of that chapter that appear in my web page at www.w2du.com that uses an example from Terman's Radio Engineers Handbook? If you haven't yet reviewed it I urge you to do it, and then if you disagree with my measured data I'd like for you to explain the reason for your disagreement.

Not near the resonant frequency of the output tuning/matching network.

He shows as little as 5 dB at 0.8 MHz offset of the external signal
from the carrier of that tx. It would be less than 5 dB for lesser
separations.

The reason that the IM performance improves for greater frequency
separations is related to the r-f bandwidth of the output network --
not the "linear" operating characteristics of the PA, or that a 50+j0
ohm load is seen by the external energy reaching the tx output
connector.

[Sorry for being a little late to the party, but I was off newsgroups most of this week.]

This thread had some discussion of adapters and I want to share my bad experience with some low-cost items, proving, once again, that you get what you pay for.

I am testing all my adapters and discarding some because the assemblies are pulling apart with very little force. One manifestation: tightening the threaded ring on a PL-259 (either cable end connector or adapter) and having the ring just continue all the way on, separating from the connector body.

One test for a future failure has been any lack of smoothness when I rotate the ring while tugging it gently. If it binds, rather than turning smoothly in my hands, it's going to fail. Also, some of the cheap connectors are press-fit together very poorly; they pull apart with only a few pounds of pull.

Most of my early exposure to coax connectors was in and around the US Navy, where reliable connectors are the rule, so I was a spoiled child.

I know your conclusion, thanks Walt.

The impedance of a perfect transmission line also is non-dissipative,
but that does not change the power dissipated in a termination of that
transmission line equaling its Zo.

Do you agree that the Mendenhall paper I have quoted shows that the
source impedance of an operating Class C vacuum tube PA and its output
tuning/matching network designed for a 50 ohm load is not, by itself,
a functional 50+j0 ohms?

Hello Richard,

We can continue mentioning measurement results, do other claims, but that may not converge. Your results show 50 Ohms output impedance, mine show other. Such results cannot be verified easily, so this remains food for endless discussions.

I decided to use another approach that can be verified by people having a (spice) simulator. I did simulations for some circuits that can be expected in the amateur world and aren't exotic. I put them over here: http://www.tetech.nl/divers/PA_impedance.pdf . Now people can figure out what it IS and get their own educated opinion. I used low frequencies to avoid discussion about the validity of the

simulations (parasitic inductances, etc).

From these simulations it is clear that small changes in load or drive level result in large change of output impedance. This knowledge resulted in my statement: "an RF PA isn't a 50 Ohms source", what was/ is heavily disputed by you.

Of course you can design to have better output VSWR under varying load or drive, but this is generally not done for systems that just have to deliver the power (transmitters).

If you want to reproduce some of the results yourself, we can compare our spice netlists. I recently added a real class C example as this was heavily discussed in another thread.

No Richard, I've not made that inference. The point I'm emphasizing is that because the output resistance of these amps is non-dissipative, no reflected power from a mismatched load enters the amp, but is totally re-reflected in the forward direction. I make no comment on whether the output resistance is 50 +j0, because when all the available power is being delivered at given grid drive the output resistance equals the load resistance, which doesn't have to be 50 + j0. Proof of that is that when the load resistance is either increased or decreased the output power decreases.

Hi Wim,

I quote a statement you made in your above post:

"From these simulations it is clear that small changes in load or
drive
level result in large change of output impedance. "

Now I agree that changing the drive level will result in a change in output impedance. However, let's say you have just adjusted the amp to deliver all the available power into a given load at a given drive level, and now you change the load, but leave the drive level and all other adjustments of the amp untouched. Are you saying this change in load changes the output impedance? If so, please explain why.

In addition, which situation has the greatest priority, data obtained from precise measurements or data obtained solely from simulations?

I have reviewed Walt's additional material at
http://www.w2du.com/r3ch19a.pdf .

Walt's load at step 1 is stated as 50+j0 without tolerance, but I accept that Walt is thorough and would have confidence that it is low in error. He reports Pf=100W and Pr=0, again accepted as indicating that the load and calibration impedance of the '43 are similar, and probably quite close to the nominal impedance, close enough for the purpose at hand.

At Step 8, he substitutes a load with measured impedance and calculated rho^2 as 0.235, VSWR(50) is approximately 3. Reported Pf=95W, Pr=25W, and on that basis rho^2=0.263. The discrepency in rho is not discussed in the paper.

A key observation between Step 1 and Step 8 is that changing from a VSWR (50)=1 load to a VSWR(50)=3 load resulted in a 5% change in observed Pf. This observation depends on the difference between two direct readings from a single instrument (the Bird 43), and the accuracy of calibration of both the Bird 43 and the 50 ohm load to their nominal 50+j0 impedance.

I have given a mathematical development at http://vk1od.net/blog/?p=1028 of why Pf should be independent of load impedance.

The observed change in Pf at 5% is rather small considering the load change, and suggests that Zs in this case is probably quite close to 50 +j0 although the experiment was limited to just one load case.

I make the "just one load case" condition because in my experience, a transmitter might exhibit insignificant change in Pf for some load variations, but for others it is signficant. The case I documented earlier is one such example.

I have made an error here, Walt reports Pf=95W, Pr=20W, and on that basis
rho^2=0.211. The discrepency in rho is not discussed in the paper.

The error has no impact on the rest of my post.

My apologies.

I have heard that it is possible to make the antenna directional by changing the arrangement of the radials.

For example, radio hams make the radials lopsided so that it transmits and receives better in a particular direction e.g. 'aimed at Europe'.

If the vertical is the active part i.e. the radiator, what do the radials do?

Are the radials a form of counterpoise i.e. one half of a dipole?

K1TTT is correct--the transmit and receive modes are reciprocally related, and thus are identical in operation. The vertical radiator is non-directional, and is the receptor in the receiving mode. The radials are not receptors and are not involved the directivity on reception.

Walt, wouldn't that non-dissipative output resistance also reflect reverse power on other close frequencies, such as those coupled from a co-located transmission system within the bandwidth of the tx output network?

If so, such external signals would never enter the transmitter, and could not cause r-f intermodulation by mixing with the main signal in the (non-linear) PA plate circuit of that transmitter to produce a 3rd order product at 2F1 - F2, and other combinations.

But such r-f intermods are a fact of life, as shown in the Mendenhall paper, and in the existence of elaborate and expensive r-f filtering hardware needed to enable several stations to operate from one location while meeting a radiated r-f intermod spec of -80 dBc -- even from one antenna!

Richard, I'm not qualified to answer your question about intermods, so
I won't even try. However, interference to the amp from radiation from
an antenna driven by another amp will not be phase or frequency
coherent with the tx receiving the interference. Perhaps that's the
reason the interfering signal gets through while the waves reflected
from a mismatch don't? In other words, could the coherent relationship
between the forward and reflected waves result in the total re-
reflection at the non-dissipative output resistance of waves returning
from the mismatched load?

Measurements made of broadcast transmitters in the engineering test lab at Harris Broadcast Division show that power reflected from a mismatched load does indeed enter the PA plate output circuitry, and change the amount of power dissipation and cooling requirement for the transmitter.

That is the reason why virtually every modern manufacturer of broadcast transmitters specifies a maximum value of load VSWR for which their maximum rated powers are permissible.

For Harris FM transmitters that value is 1.7:1 (any phase angle). As the load VSWR exceeds that value the transmitter progressively "folds back" its output power to protect itself from component damage.

Another subjective term. How near is near? All products that
Mendenhall shows in the illustration titled "RF spectrum showing
distortion products" are 30dB down and those distortion products fall
between modulation sidebands (unless you are speaking of doubling and
trippling of the carrier frequency).

Returning to the amplifier of his own design, in his classic WREK
engineering report [you seem shy of acknowledging your authority's
work here] submitted to the FCC. Now, when I say "of his own design,"
I mean by him personally, at the bench, using tools, assembling
components against his own schematic. He explicitly states:
"Distortion at 100% <= 1%." At "frequency removed from carrier" from
-35dB to -73dB out to "600 Khz and beyond."
"Harmonic and spurious radiation" at least -70dB.
"Harmonic distortion" at 100% worst case 2.3%
"Plate efficiency of 70% to 80%"
"Total efficiency of 68%" [plate power in / RF power out]
operating Class C.

And of course his statement that sends minds reeling:

"It was thus necessary to determine the plate load impedance
= (Eb - Emin) / I1
~= Eb/ Idc
~= 1000 Ohms
[Not very far from Walt's determination of 1400 Ohms from his own
bench.]
"Since this was to be coupled into a Z output of 50 Ohms, a impedance
transformation of 20:1 was needed. This was accomplished by using a
voltage divider of two series capacitors to series tune the plate
circuit."

His EIMAC reference found in other, later published papers conform to
every detail in his engineering report to the FCC and in those same
later papers. In fact, they offer a multitude of operational
parameters for a variety of tubes at many power levels, across many
bands and classes of operation.

Hello

Last night I was a little tired when I send my answers to Owen
stinging my eyes. It was too late and time to go to sleep :>)
I should tell owen he was inadvertently moving towards a logical
bifurcation's fallacy because is not absolutely true that Thevenin
theorem can not be used to calculate -for example- circuit efficience.
There are an exception to this limitation => It can be used to
efficience calculations when disconnecting the load in the original
circuit the dissipated power is null.

>is heavily disputed by you.

Hi Wim,

Your conclusion:
"Under maximum power output matching given certain drive (not
necessarily being the maximum drive), the output impedance equals the
load resistor (the so-called "conjugated match condition")."

It was not the only conclusion, but it certainly disputes what you say
above.

Given the easy access to real amplifiers available to Hams at their
own bench, and further given that they do not present any more
complexity than your own simulation; then I have to wonder why we have
wandered into strange topologies.

I am not interested in trying to follow 23 pages of dense presentation
where you could have simulated Walt's finals, validated or rejected
his data, and THEN formed your own conclusions. If this is a problem
of simulation (you don't have that tube handy) what about topology?

It looks more like a link coupled tank circuit from pre-WWII days. The
Tank Q looks to be non-existent. When I rummage through the paper I
find 4.4! This is certainly beyond the standard for PA design - and
we have swapped out of the tube into a mosfet (would you care to stick
to one objective?). Elsewhere (wandering back in tubes) I find a
value of 10.3 (elsewhere it is 11) which inhabits the lowest margin of
good design. Then an itinerant report of a cathode tank (????) whose
Q is 0.44. Q appears to be of little concern.

Again, typical Ham equipment shows Q as low as 10 - maybe, and that
would be for a dog; but those that I have seen typically fall around
15, sometimes 20. As the Z transformation in plate/drain circuits
varies by the square of Q, this is not inconsequential and it once
again has me wondering why the strange topology?

No, your paper lacks focus by trying to be all things (tubes, mosfets,
Class AB, Class C). You examine the most inconsequential details as
if they were equally important as those details that bear on your
concern. The paper lacks structure. Headings are nothing more than
feature descriptions, not argument development. There is a lot of

discussion of the idiosyncrasies of simulation - I am not interested and that discussion creates the impression of hidden errors. Really, this stuff goes into an appendix not as the object of the narrative. The graphs are pretty diversions, but they don't add much. In the software industry, this is spaghetti design.

I would prefer a conventional topology. I suppose that has come through clear. Pick one significant point, re-edit this into 4 pages and then you might have something interesting. This advice comes from one of our American writers, Mark Twain:
"If I had more time, I would have written you a shorter letter."

Miguel, when I said "cannot" I was of course meaning in the general case,
as most readers would understand.

Obviously there are cases where the efficiency calculations will be
correct, the obvious one being where the Thevnin equivalent is identical
to the original network.

If you want to make inferences about a source solely on the basis of its
Thevenin equivalent, you are on dangerous ground because you will not
always be correct.

People making the inference for example, that Zeq of a certain source
cannot be 50+j0 because the conversion efficiency of that source with a
50+j0 load is greater than 50% are wrong.

Convention has it that any report is understood to vary by 50% of the
least significant digit. There are other standards that do not wander
far from this simple expectation.

Hence 50ï¿½0.5+j0ï¿½0.5

Walt has an excellent GR 1606-A Bridge - same model as mine.

To give everyone some idea of what "Qualified" means in my former
trade, my bridge came with a traceable certificate of measurement that
tells me that me my accuracy:

" Resistance:
ï¿½[3.0 + 0.0024 ï¿½ fï¿½ ï¿½ (1 + R/1000)]% ï¿½ [(X/f ï¿½ 10000) + 0.1] Ohms
" Reactance:
ï¿½4.0% ï¿½(1.0 + 0.0008 R ï¿½ f) Ohms
"This certificate is valid only when the bridge is balanced at the
connector reference plane and when all measurements made at this plane
are corrected as outlined in para 4.4 and 4.5 in the manufacturer's
operating manual wit the exception that the capacitive reactance to
ground (Fig. 6) is computed from a value of 2.2pF. Fig. 8 should be
used for the resistance dial multiplying factor."

The correction factors easily leave behind the nominal value of 1.0
for high resistance (such as Walt's 1400 Ohms) with 5% error in the
20M band, and 60% error in the 6M band. Unless, of course, you apply
all corrections (the whole point of having the bridge calibrated).

>He reports Pf=100W and Pr=0, again accepted as indicating that the load
>and calibration impedance of the '43 are similar, and probably quite
>close to the nominal impedance, close enough for the purpose at hand.

Understanding what is available at Walt's bench, Pf could be off by
5W or 5%. The 0 reading also suffers the same 5W indeterminacy if it
is measured on the same scale (assuming he is using a Bird wattmeter
with a 100W slug).

My bridge was not remarkably far off, roughly only 1% more error in indicating the true value for resistance following corrections.

If I were to try to measure 1400 Ohms in the 20M band, I could expect it might read 1333 Ohms by dial with an error of roughly ï¿½50 Ohms.

So, between a Bird wattmeter, and it measuring power into a load with corresponding percentages of error, the we have 5% for the Bird and 3% for determining the load.

A metrologist can report these two (and there are more) sources of error by one of two ways.
1. Absolute worst case = 8% error;
2. RSS = 3.9% error
Which one picked is a function of other factors.

It doesn't take long to accumulate error and driving out variables is found only in the skill of the practice.

>At Step 8

Is a step I have no current interest in.

Richard,

You can wax on all you like, and try as hard as you like, but if the source was exactly Zs=50+j0, then the Bird 43 reading for Pf should be exactly the same.

RF measurement is as you note, fraught with problems, but here is a relatively simple case. Walt reported that he adjusted the radio on a 50 ohm load, measured Pf and Pr, then substituted another load, no other changes and reported a 5% reduction in Pf.

I will leave you to arguing wether Walt's observed 5% reduction is of any value.

Anyone who accepts that a competent measurement technician, competently using the Bird 43, can reasonably discern a 5% reduction in Pf when it should be 0% if Zs=50+j0, might question whether that observation supports the proposition that Zs=50+j0.

Owen, I don't understand where you found a 5% drop in power when you
say it should have been 0%. A 5% drop from what value to what value?
Where did you find that data? If you're referring to 100w Pf with the
50 + j0 load and then the 95w Pf the mismatched load, you've got to
understand that the source was now delivering only 75w, and the 20w of
reflected power added to the 75w = 95w. These are two separate
measurements--the first a stand-alone value and the second the sum of
two values. Is this a point you overlooked?

Hello Walt,

I wrote an article with the mathematical development for the fact that Pf (as indicated by a properly calibrated directional wattmeter such as the Bird 43) is independent of load impedance if and only if the Thevenin source impedance is 50+j0 ohms. The article is at http://vk1od.net/blog/?p=1028 .

This provides the basis for a simple go/nogo test for the hypothesis that a particular transmitter, under particular conditions, exibits Zs=50+j0.

> Where did you find that data? If you're referring to 100w Pf with the

The source is Ch 19a where you report Pf=100, Pr=0 in Step 1; and Pf=95 and Pr=20 in Step 8. I am only interested in the relative values of Pf in Step 1 (VSWR(50)=1) and Step 8 (VSWR(50)=3).

I conceded in another post that within reasonable expectations of error, and considering the load case (VSWR(50)=3), that Zs under those conditions and subject to only one load test is probably very close to 50 +j0, but probably not exactly.

In one test that I conducted with a range of loads, the drop in Pf was up to 21% with VSWR(50)=1.5, but it varied with different VSWR(50)=1.5 load angles. Whilst some values supported the proposition that Zs=50+j0, others indicated that it was significantly different. Zs did not appear to be constant, it appeared to be load dependent to some extent.

Going back to your case, if the source was 50+j0, we should expect Pf=100, and if we trust your readings from the Bird 43 as characterising the load to have rho^2=21%, we would expect the power delivered to the load to be 78.9W rather than 75W, and error of 0.2dB. Not a large error, but hard to account for entirely as instrument error.

In the measurements of an IC7000 that I made, the measured output power on one VSWR(50)=1.5 load was 82.5W when it would have been 104.6W had the

source been 50+j0, an error of 0.8dB. I opined that this test did not support the proposition that Zs was not 50+j0

Hello Owen, OK at your comment I understand, here my apologies =>

In earlier post I write:
"The final Thevenin circuit is an idealization built with an ideal
voltage source in series with an ideal resistor. This new idealized
circuit It is a new born entity whose properties are now fully
described for these only two idealized circuit elements. These are
the
virtues and the defects of reductionist models :>("

And in the first post I was thinking about Thevenin resulting scheme
ceases to represent fully the original circuit and place the problem
in a more elementary and different situation that a real world
transmitter, enabling a clear answer to much simpler scheme for the
behavior of standing waves in such elementary context. And I thought

it was pretty clear beacuse was clear enough in my mind... :>)
When one write in his own language, normally think is communicating very well the idea in his mind, until notice his partner take it in another way! Difficult is multiplied when you are trying communicate to a mind that also thinks in a different language...!
Later I realized that having formulated in terms of a simple generator in series with a resistor would not have generated a false interpretation and not difficult the flow of ideas.

I sincerely believe (correct me if I am wrong) this newsgroup does not seems make (do?) efforts enough (sufficient?) to totally (completely?) solve the more simpler cases before skip to more advanced and sofisticated considerations on more complex systems.
For example: do you (*) recognize Roy Lewallen late example in "Food for tought" assuming (or conceding that) as not representing a real rig but a simple constant voltage source in series with a resistor, at least? to give some credit to his ideas Until now, I could not know...
(*) I do not know how clearly denote plural in "do you"

73 Miguel - LU6ETJ.
Here 04:46 LT - I am not responsible for anything written by me :>)

The relevant illustration applying to the generation of r-f intermodulation from external signals was linked in my original quote from Mendenhall's paper on this subject in this thread, which link I repeat below.

It shows that the "tunrnaround loss" for external signals 0.8 MHz offset from the carrier is as little as 5 dB, just as I posted.

By limiting limiting your understanding to the performance of an r-f amplifier having no external influences you are missing the point of the Mendenhall paper I referred to.

In that article, Roy says "My commercial amateur HF transceiver is probably typical of modern rigs in that it produces a constant forward average power into varying load impedances provided the impedance isn't extreme enough to cause the rig to severely cut back its power output."

Assuming that "constant forward average power" means 'as would be indicated on a directional wattmeter calibrated for Z=50+j0', if that is true for all load impedances that Pf is constant (within limits), then it is evidence that Zs=50+j0 (within those limits).

He goes on to say "It turns out that a linear model of my transmitter (without a transmatch) over its non-shutdown range is very simple it's just a voltage source in series with a resistance." Subject to the conditions I stated in the previous paragraph, that is correct, but that whilst that model can be used to determine behaviour of the external load, there are limits to the inferences that can be drawn about the internals of the transmitter, including as mentioned in earlier posts, internal dissipation and efficiency. Roy acknowledges that in the next paragraph. Only a mischief maker would represent Roy as meaning otherwise.

From my own experience, I don't agree that HF ham rigs typically produce constant Pf into varying loads. Walt's transmitter measurements that we are discussing do not show constant Pf, though the change is fairly small. But this is a practical measurement project for yourself, don't be put off by the attempts to discredit measurements with anything but traceable calibration.

> (*) I do not know how clearly denote plural in "do you"

I am not the expert that others are on English language, and we speak a version of English closer to the English here... but "you" is plural and singular (but if followed by a verb, it is treated as plural eg "you are correct"), and you could say to a group "do you agree", though some people may say "do you all agree" or "do y'all agree", though those might be seen as asking each member of the group rather than collectively.

Sal's right - it's down to the quality of the item. I've seen some poor BNCs, but many PL-259s which were REAL rubbish. I expect it's because many of them are used for CB - and price is the usual decider there.

I've standardised on 50R BNCs for everything. Usually Amphenol or Greenpar - the extra cost is insignificant, compared to rig prices these days. Why 50R - the only reason is that the sockets are more robust.

Ready made BNC cables have been a disappointment - they are usually crimped, and the crimps seem to relax with age. Cables can pull out,

given a bit of a tug. I use solder/clamped connectors and always solder
the braid to the clamping sleeve. Never had a failure.....

> If the vertical is the active part i.e. the radiator,
> what do the radials do?

Buried radials collect the r-f earth current produced by radiation from a vertical monopole, and which are present in the earth out to about a 1/2-wavelength radius from the base of the monopole.

The net resistance to those earth currents returning to the ground connection of the antenna system at the base of the monopole is much less than when no buried wires are used, because the wires provide an alternate path with much better conductivity than provided by the earth itself.

The resistance to earth currents in that return path is in series with the radiation and other resistances in the antenna system. For best system radiation efficiency, it needs to be kept as low as possible (or practical). In the MF band, a set of 120 equally-spaced, ~1/4-wave, buried radials surrounding the radiator produces an r-f loss of less than about 2 ohms, regardless of the actual conductivity of the soil in which they are buried.

Installing buried radials over a limited azimuth sector (say, 180 degrees) won't change the directional characteristics of the monopole -- it will only reduce the value of field it produces, as a result of higher losses in the earth area around the radiator where displacement/conducted r-f ground currents are high.

But other things equal that radiation pattern still will be circular, just a smaller circle.

I agree completely with the second sentence. But the first is in
error. A directional wattmeter will indeed show 50W forward and 50W
reflected on a line with constant DC voltage and 0 current. I'll
start by providing support for your second sentence and then get
back to reflected power.

Choose an arbitrary point on the line and observe the voltage. The
observed voltage will be a function of time. Let us call it V(t).
At the same point on the line, observe the current and call it I(t).

The energy flowing (i.e. power) at this point on the line will
be P(t)=V(t)I(t). If the voltage is measured in volts and the current
in amps, then the power will be in joules/s or watts.
We can also compute the average energy flow (power) over some
interval by integrating P(t) over the interval and dividing by
the length of the interval. Call this Pavg. For repetitive
signals it is convenient to use one period as the interval.

Note that V(t) and I(t) are arbitrary functions. The analysis
applies regardless of whether V(t) is DC, a sinusoid, a step,
a pulse, etc.; any arbitrary function.

To provide some examples, consider the following simple setup:
1) 50 ohm, Thevenin equivalent circuit provides 100 V in to an
open circuit.
2) The generator is connected to a length of 50 ohm ideal
transmission line. We will stick with ideal lines for the
moment, because, until ideal lines are understood, there
is no hope of understanding more complex models.
3) The ideal line is terminated in a 50 ohm resistor.

Set the generator to DC:
V(t)=50V, wherever it is measured on the line
I(t)=1A, wherever it is measured on the line
P(t)=50W, wherever it is measured on the line
Pavg=50W

No disagreement, I hope.

Set the generator to generate a sinusoid:
V(t)=50sin(wt)
I(t)=1sin(wt)
P(t)=25+25sin(2wt)
Pavg=25W
describes the observations at any point on the line.
Measurements at different points will have a different
phase relationship to each due to the delay in the line.
Note carefully the power function. The power at any point
on the line varies from 0 to 50W with a sinusoidal
pattern at twice the frequency of the voltage sinusoid.
The power is always positive; that is, energy is always
flowing towards the load.

Now let us remove the terminating resistor. The line is
now open circuit.

Again, set the generator to DC. After one round trip
time, the observations at any point on the line will
be:
V(t)=100V
I(t)=0A
P(t)=0W
Pavg=0W

The story for a sinusoid is more interesting...
The observations now depend on the location on the
line where the measurements are performed.
At a current 0:
V(t)=100sin(Wt)
I(t)=0A
P(t)=0W
Pavg=0W
At a voltage 0:
V(t)=0V
I(t)=2sin(wt)
P(t)=0W
Pavg=0W
Halfway between the current 0 at the load and the
preceding voltage 0 (that is, 45 degrees back
from the load:
V(t)=70.7sin(wt)
I(t)=1.414cos(wt)
P(t)=50sin(2wt)
Pavg=0W
This tells us that for the first quarter cycle of the
voltage (V(t)), energy is flowing towards the load,
with a peak of 50W, for the next quarter cycle, energy
flows towards the source (peak −50W), and so on, for

an average of 0, as expected.

For a sinusoid, when the load is other than an open
or a short, energy flows forward for a greater
period than it flows backwards which results in a
net transfer of energy towards the load.

At the location of current or voltage minima on
the line, energy flow is either 0 or flows towards the
load.

All of the above was described without reference to forward
or reflected voltages, currents or power. It is the basic
circuit theory description of what happens between two
networks. It works for DC, 60 HZ, RF, sinusoids, steps,
pulses, you name it. If there is any disagreement with the
above, please do not read further until it is resolved.

Now it is time to introduce forward and reflected waves to
the discussion. Forward an reflected waves are simply a
mathematical transformation of V(t) and I(t) to another
representation which can make solving problems simpler.

The transformation begins with assuming that there is
a forward wave defined by Vf(t)=If(t)*Z0, a reflected
wave defined by Vr(t)=Ir(t)*Z0 and that at any point
on the line V(t)=Vf(t)+Vr(t) and I(t)=If(t)-Ir(t).

Since we are considering an ideal line, Z0 simplifies
to R0.

Simple algebra yields:
Vf(t)=(V(t)+R0*I(t))/2
Vr(t)=(V(t)-R0*I(t))/2
If(t)=Vf(t)/R0
Ir(t)=Vr(t)/R0

Now these algebraically transformed expressions have all
the capabilities of the original so they work for DC,
60 HZ, RF, sinusoids, steps, pulses, you name it.

Some people look at the expression If(t)=Vf(t)/R0 and
think it looks a lot like a travelling wave so they decide
to compute the energy being moved by this wave:
Pf(t)=Vf(t)*Vf(t)/R0
Pr(t)=Vr(t)*Vr(t)/R0

So let us explore the results when applied to the DC examples from
above.

Terminated with 50 ohms:
Vf(t)=50V
If(t)=1A
Vr(t)=0V

Ir(t)=0A

Pf(t)=50W
Pr(t)=0W

This all looks good, no reflected wave and the appropriate amount of energy is being transported in the forward wave.

Let us try the open ended line:
Vf(t)=50V
If(t)=1A
Vr(t)=50V
Ir(t)=1A

which yield
V(t)=Vf(t)+Vr(t)=100V
I(t)=If(t)-Ir(t)=0A

which is in agreement with the observations. But there is definitely a forward voltage wave and a reflected voltage wave. Carrying on to compute powers:
Pf(t)=50W
Pr(t)=50W
and
P(t)=Pf(t)-Pr(t)=0W

So there you have it. The interpretation that the forward and reflected wave are real and transport energy leads to the conclusion that on a line charged to a constant DC voltage, energy is flowing in the forward direction and energy is flowing in the reflected direction.

Because it is obvious that there is no energy flowing on the line, this interpretation makes me quite uncomfortable.

Now there are several ways out of this dilemma.

Some say they are only interested in RF (and optics), and that nothing can be learned from DC, steps, pulses or other functions. They simply ignore the data and continue with their beliefs.

Some claim that DC is special, but looking at the equations, there is no reason to expect the analysis to collapse with DC.

The best choice is to give up on the interpretation that the forward and reflected voltage waves necessarily transport energy. Consider them to be a figment of the analysis technique; very convenient, but not necessarily representing anything real.

As an added bonus, giving up on this interpretation will remove the need to search for “where the reflected power goes” and free the mind for investment in activities that might yield

meaningful results.

Hello Walt,

I think it does, changing the load will change the output impedance.
The root cause is that under conjugated match conditions (given fixed
input drive, constant supply voltage, etc), the active device is

operating on the edge of voltage saturation.

When you reduce the load resistor (parallel representation, and seen from the plate), the RF plate voltage drops, causing the valve to operate more like a current source. Increasing the load resistance will result in voltage clipping, so plate voltage rise with increasing load resistance is limited.

One can also say that (under voltage saturation), during a small portion of T, the plate voltage is shorted to ground via about 120 Ohms (derived from DC characteristic of 6146 valve).

I added page numbers to the document (it is at the same location). When you look at page 3 you can see the simulation results. Output impedance (based on deltaV/deltaI with different load resistors) changes from above 9 kOhms to below 1000 Ohms. For load changes of less the VSWR = 1.2.

When the valve is operated below voltage saturation (for example due to decrease of load resistance or drive reduction), the output impedance is less dependent on load change and the amplifier will more or less behave like a linear circuit. You can see this on page 8. That table is for a situation where the plate voltage is below the amplitude that causes voltage saturation of the tube. Look also to the power supplied to the load, there is no conjugated match.

Regarding simulation.
I am fully aware of the limitations of simulation. I did compare the data sheet curves with simulated curves first. The simulated one has a somewhat steeper transition between current saturation region and voltage saturation region. This will result in some more output impedance change versus plate RF voltage, but doesn’t make the simulations useless. the low Q in the cathode was just for making the cathode voltage more sinusoidal to enable to guess the actual input power.

My observations resulting in my statement regarding output impedance of amplifiers were from the time that I never simulated a PA. They are from measurements and reasoning starting from the time that I was in school designing a solid-state (BLW76 bipolar transistor) amplifier with third harmonic peaking. Referencing to measurement will likely result in endless discussions, even when publishing the full details. To avoid this, I did some simulations (with the risk that people may waive this also).

In my opinion it is too easy to waive results that are from simulation as some other people are trying. Simulation is standard practice in the design flow.

I hope you concluded that the simulations do not dispute most of your findings, even the conjugated match with high efficiency is still standing (which is disputed by others). The only thing I tried to support is that many real world amplifiers under practical operating

conditions do no show output impedance equal to the specified load and that therefore answering "what happens with reflected energy?" is not just a simple transmission line problem. I therefore added also a simple non-exotic mosfet stage for FM/CW operation as many people use solid-state PAs.

Best regards,

23 pages is not that much as graphs and circuit diagrams dominate. If
you can provide me a circuit diagram I will figure out whether I can
simulate it or not.

Fully agree with the low cathode Q, therefore it doesn't affect the
simulations results significantly.

Tell me what Q I should use (evt, give me component values) in the
simulation, and I will change it for you.

>

This is to support my statement that under real world amateur
conditions many PAs do not obey ZL = Zout*. If I have some time I will
add a push-pull transfomer coupled amplifier also.

You examine the most inconsequential details as

simulation is general practice in the design flow, I know it has
limitations. Of course I could use ADS, but most people don't have
that at home, so I decided to use spice as this is used by many.

If you believe I am so wrong, why don't you present some simulations
to show that my original statement is completely wrong?

You would do well to download EZNEC and give your ideas a try. You will
find that the best directivity comes with only one radial. There is
about 4dB difference between the side and front(or back) of the *total*
radiation pattern. However, you will see that this directivity comes at
the expense of increasing the horizontal polarization and decreasing the
vertical polarization. This might be okay, depending on your
circumstances. That's why I suggest you use EZNEC -- only you know what
is acceptable for your case.

Good luck.

No, it was non-existent. The source I referred to was Roy's *specified
source* in his food-for-thought article on forward and reflected
power. Roy used his *specified source* to do his power calculations.
Contrary to what you asserted, Roy certainly did "make an inference
about the internal dissipation of the source". The fact that Roy's
specified source doesn't resemble a ham transmitter is irrelevant.

John, are you using EZNEC to model radials in the ground or above-ground? If you're modeling in-ground radials then you must be using EZNEC incorrectly t o obtain directivity other than omni-directonal, because the directivity of any vertical radiator is equal in every direction, regardless of the number of radials, zero or an infinite number. In other words the radiator is omni-directional. On the other hand, if you're modeling an above-ground radiator with only one radial, then of course the radiation will include both vertical and horizontal components, which result in a polarization angle other than either vertical or horizontal and will likely have radiation that is not omni-directional.

Ah, but you said you could calculate "them", meaning at least two
voltages. You have calculated one voltage to be zero. So what is the
value of one of the other voltages when the Z0 is unknown?

> wary of stating so simply.

I should have used arrows rather than equals signs.
But it's basically a manifestation of Chu's idea combined with practical materials.

Chu proposed the concept relating directivity and stored energy and physical size. A passively excited multi element array (like a Yagi) has to transfer energy from element to element to work, and it follows the characteristics outlined by Chu. And anything with circulating energy that gets carried by a conductor is going to have high(er) I2R losses than something that doesn't.

it may be true for a specific type of
> antenna, MAYBE Yagi's, MAYBE rhombics or or close coupled wire arrays,
> but some of the most directive antennas are parabolic dishes which i
> would expect to have very low Q and extremely low losses.

Interesting case there. Loss isn't all that low (typical parabolic antennas with their feed have an efficiency of 50-70%), although it IS low compared to the directivity. And, in fact, there's not much stored energy (so the Q is low). On the other hand a parabolic antenna is physically very large compared to a wavelength, so the Chu relationship holds. I'd have to think about whether one can count the energy in the wave propagating from feed to reflector surface as "stored", but I think not. Probably only the E and H fields at the reflector surface.

you could
> also have an antenna with very high Q, very high i^2r losses, but very
> low directivity, so i would be careful about drawing a direct link
> between the two.

Yes.. you're right.. the relations set an upper bound on what's possible.. That is, for a given directivity, you can get either small size and large stored energy (the Yagi-Uda or W8JK), or large size and small stored energy (the parabolic reflector and feed). As you note, a dummy load has very low directivity.

Hi Wim,

I'm glad you wish to examine this more. I will send you Mendenhall's
400W FM design done 42 years ago to this month and nearly day. I will
also send a partial schematic for Walt's TS-830s.

Mendenhall's is not very different from your own model except with a
far more powerful VHF Tube, however, it is a tetrode design too.
Walt's is a pair of pentodes. See what you can do.

>Fully agree with the low cathode Q, therefore it doesn't affect the
>simulations results significantly.

Why a Common Grid design for a tetrode tube?

>Tell me what Q I should use (evt, give me component values) in the
>simulation, and I will change it for you.

15 is one that Terman cites, and Mendenhall cites Terman, and Walt's
(if I recall correctly) also find a similar value. Given your
especially low frequency simulation, component values are way out from
those commonly encountered in HF/VHF work.

>> No, your paper lacks focus by trying to be all things (tubes, mosfets,
>> Class AB, Class C). ï¿½
>
>This is to support my statement that under real world amateur

Then you should do the finals deck for a transistor rig for that
topology. It would bring you into the 21st century (even if the
details still date from the 1970s). You will also find more
simulation options.

>simulation is general practice in the design flow, I know it has
>limitations. Of course I could use ADS, but most people don't have
>that at home, so I decided to use spice as this is used by many.

One of the titans of linear design, Bob Pease of National
Semiconductor had little sympathy for those who discovered the

problems of simulation. However, those who read his work were sure to avoid pain and trauma. Consult:
http://www.national.com/rap/

Having said that, it is somewhat ironic that we all use simulation for antennas - so we are all aware of limitation and possibility. I have used many simulators from a spectrum of disciplines.

>If you believe I am so wrong, why don't you present some simulations
>to show that my original statement is completely wrong?

You have more time and passion for it. I have already had a career in testing these issues specifically and proof is at the bench. I was trained to demanding methods for this and I worked with the most accurate instruments in the world. However, I don't expect equal results. If you wish to work further with the two schematics I send you, then that would interest me far more than the banalities of photonic explanations and spreadsheet solutions.

I am not saying anything you have done is wrong, I am saying that your style is getting in the way of communication. It reads like a detective novel, not a like presentation. You discover conclusions, you don't seem to test for expectations. Surprise and mystery arrive haphazardly through the narrative. Inconsequential details are mulled over like Holmes describing the characteristics of cigar ash to Watson.

You are trying to do too many things in one place and the topic begins to blurs and the goal is distracted. For instance, this thread's subject line of "what happens to reflected energy?" is never summarized in your final conclusion - that is not good reportage. I went to that last section and saw that discussion missing. Closer examination revealed it by parts as seemingly trivial observations.

For style, start with a good grounding. Establish a base line. Do a Monte Carlo analysis of a known design with known characteristics. Then introduce a hypothesis tied to one variable. Push the variable and note how it either conforms or strays from your hypothesis. Present your work. Have a discussion to shake out problems of understanding (from anyone). Then move on to either shift the topology, or further stress the existing design. Build on a solid foundation.

Schematics will follow as soon as I can make their file sizes suitable for email servers (about 1-2 MB).

I suppose this will be buried where nobody will read it...

I realized that with the nice instrument-grade directional couplers
that came with a new 100W RF power amplifier, and with the other
equipment on my bench, I can measure RF amplifier/transmitter source
impedance relatively easily and with good accuracy. I strongly
suspect the accuracy will be limited first by how well the setup of
the transmitter/amplifier can be duplicated, and not by the
measurement instruments.

I won't go through the whole test setup, but just say that
substituting an open or short for the connection to the transmitter
yields the expected amplitude return signal, and terminating the line
in a precision 50 ohm calibration standard yields a 47dB return loss,
for the frequency I was measuring (nominally 7MHz, for this first
measurement). The measurement involves sending a signal offset from
the nominal transmitter frequency by a few Hertz at about -20dBm
toward the transmitter, and looking at what comes back.

Measuring a Kenwood TS520S, set up for about 70 watts output, ALC
disabled, operating as a linear amplifier somewhat (about 30 watts)
below its maximum output: result is 56+j16 ohms at the output UHF
connector on the TS520S. That's about 1.4:1 SWR, and at some point
along a lossless line, that's equivalent to about 70+j0 ohms: not
terribly close to 50 ohms. I'm not going to bother with a detailed
error analysis presentation, but I'm confident that the amplitude of
the return loss is accurate within 0.1dB, and the phase angle within

10 degrees, to better than 99% probability.

I may make some more measurements with different amplifier setups and at different frequencies, but for now, that's it...

Cheers,
Tom

This is repetitive without being informative. I am satisfied with
Mendenhall's clear statements about plate resistance in how to fine
tune finals - a paper that is obviously on-topic. I am satisfied with
his WREK design (as was the FCC). I see he observed standard methods
of design and cites accessible authorities that guide industry. I
don't need to elaborate what he offers by mincing around the issue
with interpretation, inference, and suggestion.

To offer what you think is contrary evidence goes well toward
impeaching your own authority. There is no amount of discussion or
even agreement that can balance that contradiction. From the content
of your other discussion, you are arguing both sides, or you are
turning this on the pivot of an opaque detail known only to you.

I am satisfied that the general readership has all the details. Or
could ask for them if this was interesting.

Because I built such circuit myself based on two PL519 television
tubes and to reduce the number of runs to tune the amplifier in
simulation (I still need some time to work also).

Over here 3.6 MHz is an amateur band, we may even go lower than that.
I will change the real class C ciruit to Q = 15. Q = Rload/XL?

I have very limited time for this, so we have to keep it very
efficient.

Except the high Z value for the Common Cathode amplifier, all results
are as expected. Otherwise I did not make my statement on the output
impedance of PAs.

You disputed my statement on Zout and came up with the "what IS it"
attitude, I only provided information so that other people can get
their own opinion. I prefer to keep the focus on that.

Before I am going to spend lots into time this, some points:

1. Do you accept the "measuring" method with injecting a signal with
slight frequency difference as mentioned in the document?

2. Do you accept the way of presentation (envelope change versus time
and converted to output VSWR as used in the document)?

3. Do you accept B^2 spice A/D professional, version for as suitable
platform?

If we cannot agree on this, it is of no use to continue.

I limit the simulation to low HF frequencies as based on a circuit
diagram alone we cannot guess the parasitics for high HF/VHF use and
this may be food for more discussion. Please also mention what
components you want into the simulation as simulating a full TS830
will take to long.

All relevant info will be made available to the group, inclusive
original circuit diagrams and the diagrams I used for simulation. I
hope that I can get a suitable simulation model for the tubes.

Regarding circuit diagrams, can you reduce the color depth (gray scale
or B/W) and convert them to PNG as this is non-lossy coding.

I am looking forward to the results.

Best regards,

Wim

Making some assumptions about a sensible implementation for the test, an interesting test Tom, thanks for the writeup.

One of the interesting propostions emerging in the discussion is that Zs may be dependent on drive level. Your test setup would be an interesting one to explore that effect (changing drive level alone, no other adjustment or change).

In my own tests looking for Pf constant (independent of load changes), I have noted that I get different results from the IC7000 at different drive levels. Not surprising, as the gain of the active devices are likely to change significantly in the upper half of the rated power range, and the effects of either current or voltage saturation are likely to be manifest at near rated output, and power control loops at maximum output.

If Zs is dependent on drive level in a significant way, then one must ask what is the application of Zs in the case of an SSB telephony transmitter.

>

ok, p(t)=0w, i=0a, i connect my directional wattmeter at some very
long time after the load is disconnected so the transients can be
ignored and i measure 0w forever. there is no power flowing in the
line.

so you have derived voltages and currents at a couple of special
locations where superposition causes maximum or minimum voltages or
currents... this of course ONLY works after sinusoidal steady state
has been achieved, so your cases of connecting and disconnecting the
load must be thrown out. and how do you find a maximum or minimum

when the load is matched to the line impedance? standing waves are
always a trap... step back from the light and come back to the truth
and learn how to properly account for forward and reflected waves with
voltages or currents and all will be revealed.

>   Ir(t)=Vr(t)/R0
>
> Now these algebraically transformed expressions have all
> the capabilities of the original so they work for DC,
> 60 HZ, RF, sinusoids, steps, pulses, you name it.

hmmm, they work for all waveforms you say... even dc?? ok, open
circuit load, z0=50, dc source of 100v with 50ohm thevenin
resistance...

If(t) = 100/50 = 2a
Ir(t) = 100/50 = 2a

so there is a reflected 2a current you say? where does that go when
it gets back to the source? we know that when the 100v source is open
circuited as it must be in this case that it develops 100v across its
terminals... sure doesn't seem like any way that 2a can go back into
the source. it can't be reflected since the source impedance matches
the line impedance. so where does it go? maybe those simple
algebraic expressions have to be reconsidered a bit.

well, maybe i missed something... lets look at the voltages:

Vf(t)=(100+50*2)/2 = 100
Vr(t)=(100-50*2)/2 = 0

hmm, you do seem to get the right constant voltage... but it kind of
messes up your power flow since Vr=0 there can be no power in that
reflected wave, so it really doesn't make it much of a wave.

but wait, the equations must be consistent so

Ir(t)=0/50

So there really is no reflected current... but there is forward
current? so where does that forward current go if there is no load?
it doesn't reflect back if Ir=0... does it just build up at the open
end? going to be lots of trons sitting there after a while.

Comparing to my table of results for my own TS430S, with similar
initical conditions, that is well within the range of measurements I
have taken.

Hi Wim,

I got only a hint of what you were trying to do because it was buried
in so much conflicting agendas.

However, my first impression was that it looked worth discussing. My
second impression was that it was not needed. Still, that is worth
discussing too.

>2. Do you accept the way of presentation (envelope change versus time
>and converted to output VSWR as used in the document)?

I hadn't the slightest idea what that was all about. Like I said, too
many things going on. From your email, it sounds like too much
complexity to accomplish what was done with meter indications.

For others, this might be found in the section called "Output Tuning"
in:
"Fine Tuning FM Final Stages," by Mendenhall (google for a link or
email me for a copy).

>3. Do you accept B^2 spice A/D professional, version for as suitable

We will resolve the details offline. I would encourage you to save effort (we both have things to do) by doing a "quick and dirty" first pass just to see how little we may have left to do (it could be that simple). There is more to read than there is to simulate.

For others, the material I have linked Wim to probably tips the download scale at 50MB. 44 MB is one document alone that others here might find useful:
"EIMAC Care and Feeding of Power Grid Tubes" 44MB at:
http://www.g8wrb.org/data/Eimac/care_and_feeding_of_power_grid_tubes.pdf

It will brush away the cobwebs.

Tom, you stated earlier that you measured the source impedance of a TS520S transceiver by inserting a somewhat off-resonance signal into the output terminals when the rig was delivering 70 watts, and the source impedance was measured as 56+j16 ohms. However, you chose not to describe the setup or the procedure for obtaining this data.

I'm hungering to learn of the setup and procedure you used, because I'd like to know what reflection mechanism gave a return signal that could be discriminated from the 70w output signal from the transceiver.

In his Nov 1991 QST article Warren Bruene, W5OLY, used what I believe is a similar procedure, in which he claims he measured the Rs that he called the 'source impedance' of the RF amp. He used his measurements in asserting that because his Rs didn't equal RL there could be no conjugate match when the source is an RF power amp. I have never believed his procedure and measurements were valid, and I still don't. So if your setup in any way resembles what Bruene presented in his QST article I would like to know how you can justify a procedure that involves inserting an off-set frequency signal rearward into an operating RF power amp to determine the source impedance.

Hi, Walt -

Above ground about 2 wavelengths and, yes, the vertical component is omnidirectional. It is the horizontal component that gives some directivity as you said. I think I used the wrong phrase above. I said, "increasing the horizontal polarization" when I probably should have said "increasing the horizontally-polarized field". Ditto for the vertically-polarized field.

If I still have it phrased wrong, please help. This is the sort of thing that happens when you turn an old fart loose with a simulator.

OK...

So let's consider making a load-pull measurement of source impedance.
Since we're trying to resolve both resistance and reactance, we need
to change the load in at least two directions that have a degree of
orthogonality. But we could also change the load over a range of
values. For example, we could connect a 51+j0 load directly to the
output port we're trying to measure, and then connect it through
varying lengths of 50.0 ohm lossless coax. 45 electrical degrees of
line would shift the phase of the 51 ohm load so it looks instead like
49.99-j0.99 ohms. 90 electrical degrees shifts the 51 ohm load to
49.02+j0 ohms, and so forth. Measurements of the varying amplitude

output with those loads will give us enough information to resolve the source resistance and reactance and open-circuit voltage.

For a 51 ohm load on a 50 ohm line, the reflection coefficient magnitude is 1/100, so if the transmitter is putting out 100Vrms forward, the reverse is 1Vrms.

Now consider a method to change the line length that doesn't use individual sections that have to be patched in and out, but rather uses a "trombone" section that, in theory anyway, could range from zero length to essentially infinite length. Picture that trombone section getting longer at a fixed rate, so now the load is rotating around a circle on the linear reflection coefficient plane (which is, by the way, exactly the same plane the Smith chart is plotted on); the circle is centered at zero and is a constant 1/100 amplitude, with linearly varying phase. So the 1Vrms reverse wave on the line of the 100Vrms forward example arrives back at the amplifier at continuously varying phase. Imagine that the phase shift is 360 degrees in 1/100 of a second. Now note that the reverse wave corresponds _exactly_ to a wave offset in frequency from the forward wave by 100Hz. If the line is continuously lengthening, the offset is negative; if the line is shortening instead, the offset is positive.

Now, from the point of view of the amplifier, can that scenario be distinguished from one in which I have a perfect 50 ohm load that absorbs all the transmitter's output, and a method to introduce a "reverse" 1.00Vrms wave into the line at a frequency that's offset from the transmitter's output by 100Hz?

If you believe that the amplifier can distinguish between those two scenarios, I fear we have nothing more to discuss.

Cheers,
Tom

Thanks Owen. I believe I quite understand your kind explanation and
reasons, but I am not sure if I can ask my question well enough
indeed!. I beg your patient.
I am not interested yet to make questions about real rigs, but reduce
at first only one specific problem at the most simple theorical model
I can think: an ideal constant voltage source in series with an ideal
resistence loaded at first with simple resistive loads connected
directly and late via ideal lossless TL of differents simple
wavelenghts 1/2, 1/4, 1/8 (I have formed idea about this, but I am not
interested in my concept but your concept about it).
For example, I want to know if you (all) would predict identical Rs
and Rl dissipation in that reduced and theorical context with direct
and remotely connected loads (vinculated via TL).

To this point K1TTT -seem to me- tell me you all would agree to settle
the problem with Telegrapher's equations to obtain TL input Z and then
apply simple circuit theory solution to calculate Rs-Rl dissipation
(before begin Thevenin misleading issue).
I do not want to advance more from here for fear to complicate the
question with my translation.

Thanks again.

After I got out of the Navy, I worked as a Marine Electrician, installing
equipment on Navy ships. My foreman told me that it is rarely done, but the
Navy can perform a Quality Assurance "pull test" of 25 lbs on a connector.
I think that's a lot of pull for a connector to withstand.

Yes, if you are looking for a steady state solution, that is a valid
solution, and almost the easiest solution.

If you are using lossless lines, then the solution can be simpler than the
Telegrapher's Equation which uses hyperbolic trig functions. Simple trig
functions suffice if the line is lossless... but of course, the hyperbolic
functions will also work.

The reason I said "almost the easiest solution" above is that a trig based
simplification of the Telegrapher's Equation is simpler than the hyperbolic
Telegrapher's equation.

Implicit in this is that for the steady state, it doesn't matter how an
external network dictates V/I (Z) at the source/load terminals, whether or
not transmission lines are involved, or their length, the power delivered
by the source to its immediate load is determined by Veq, Zeq of the
source, and Zl of the load.

If an experiment indicates othewise, the experiment is flawed (eg something
is wrong with the assumed values for circuit components, measurement error
etc).

Taking Walt's example, he connected three 50 ohms loads in parallel, then
attached a nominal 50 ohm line of 13.5° electrical length. If you use TLLC

(http://www.vk1od.net/calc/tl/tllc.php) to solve this problem at 4MHz using RG213 (though I don't know what he used), Zin is 17.78+j10.58. A lossless solution will have very slightly lower R. Walt measured 17.98 + j8.77 which suggests that the load at the end of the 50 ohm line was not exactly 16.6667+j0, or the line a little shorter, Zo off spec etc.

Whilst the above focuses on steady state analysis, understand that steady state analysis is not appropriate for some types of transmitters, but for systems where the transmission line propagation delay is small compared the the highest modulating frequency, steady state analysis should be adequate.

Owen

Hi Walt,

For every hundred pundits there is at least one bench worker that is more productive than them all. Of course I am being facetious, it is probably closer to a thousand.

In the SARL Forums at:
http://www.sarl.org.za
search for the 19/04/2009 posting by ZS6BIM with the thread name:
Measuring the Output Impedance of a 100W Class AB HF Linear Amplifier
Plenty of data and charted and screen shots of O'scopes.

A very intriguing use of directional couplers (much as I would expect Tom to have done). It seems to me I've directed you to similar work (the rat-race-like method seems familiar to our email discussion some dozen years ago).

The writer had the cojones to use his vector voltmeter at the transmitter's antenna terminal. Back in 1997 I used my GR bridge to look down the throat of the fire breathing dragon (TS430S) while it was asleep and got similar results:
10 MHz 74 Ohms
14 MHz 74 Ohms
18 MHz 60 Ohms
21 MHz 37 Ohms
25 MHz 35 Ohms
28 MHz 48 Ohms
29 MHz 70 Ohms

33e RADIO FLEA MARKET in BEETSTERZWAAG on 28 May 2011

The radio flea market takes place to - 28 May 2011. Do you look for an exotic transistor kit or a super recipient, fixed and do manufacture kit...
or do meet of radio friends? Dan comes Saturday 30 May to the Friese radio market into Beetsterzwaag!

Many thousand visitors come each year from the entire Netherlands and Europe to this radio flea market spectacle, approx. 100 dealers, with most diverse articles, like transmitters, recievers, power supplies, antennas, software, hardware and literature.

Additionally of businessmen in the place also a flea market with many attraction organized for large and small. There are some sales desks free at the moment on the radio flea market, you can reserve by telephone & email, contact on to take with the executive committee. Down are these addresses.

How does one find after Beetsterzwaag? From direction Apeldoorn = > Zwolle = > Meppel = > Heerenveen = > Drachten, departure after Gorredijk Tijnje comes departure (28) Beetsterzwaag.

From direction Bremen = > Groningen = > Drachten = > Heerenveen, departure after Drachten Haven comes departure (28) Beetsterzwaag.

On 2mtr, 145,700 Digi Heerenveen can one to instruct leave themselves. Inlet is from 09:00 to 16:00 MESZ, into which Cafeteria one also boarded into this time.

This whole is organized of VERON FRIESE WOUDEN. Cordially Welcome in Friesland on the 33e FRM!

Look for more information at the site: www.frm.a63.org

IMO, the error that Bruene made is similar in concept to the some of the errors being made here in this thread. Many people assume that a simple reflection is the only way to change the direction and momentum of an EM wave in a transmission line. In "Reflections", Sec 4.3, Reflection Mechanics of Stub Matching, you describe the role of wave cancellation associated with interference as a mechanism for redistributing reflected energy back toward the load. You said, "Wave interference between these two complimentary waves at the stub point causes a cancellation of energy flow in the direction toward the generator." It seems obvious to me that your "virtual short" reflection at a Z0-match point is a combination of ordinary wave reflection and interference patterns adding up to zero energy flowing toward the source. Obviously, interference can also happen inside a source.

Redistribution of energy can occur associated with destructive/constructive interference inside the source and has an effect on the V/I ratios, i.e. on the impedances. Bruene's pinging method completely ignores the role of interference at the source. The Z = (Vfor+Vref)/(Ifor+Iref) impedance for coherent waves may be a completely different value than for the non-coherent pinging waves.

Miguel, some posters here don't seem to realize that your questions involve a source like the one specified by w7el in his foot-for-thought article. That source may bear little resemblance to an actual ham transmitter but it is the one w7el specified and it can be easily analyzed for source resistor dissipation and tracking of the reflected energy.

Hello Tom,

The method of constant varying phase of a mismatch to determine output impedance I use in my simulation also (because it saves me time). I use a second source with some frequency offset instead of the trombone as you described (the trombone I cannot implement easily in my pspice package).

When you change the phase very slowly, a soft power supply may change voltage during the slow variation (as a load change may result in a DC supply current change). When the difference frequency is sufficiently high (for example 200 Hz or more), the electrolytics will keep the supply voltage constant during all phase "steps". Therefore there may

be slight difference between measurement with a set of loads with increasing phase and the RF injection method (for example with vector analyzer).

I checked the injection method in simulation for linear circuits (with both real and complex output impedance), linear active circuits, and power circuits. I couldn’t find any flaw in the method. So I think your reasoning is valid.

Some results applicable to PAs, inclusive the implementation in simulation are in: http://www.tetech.nl/divers/PA_impedance.pdf. Note that I determine the reflected voltage by means of interference with the amplifier's output signal (envelope detection) as this saves me from making a narrow band filter that results in very long run times.

I am now simulating a circuit with 6146 valve and pi-filter output (50 Ohms) and I will add it to the document.

Best regards,

I chose that length so that the transmission line would have no effect on the impedance seen by the transmitter. As I've said many times, and you've continually disagreed with, increased dissipation and/or damage at the transmitter is due to the impedance it sees, and not by "reflected power". The example I gave keeps the transmitter load impedance constant while changing the "reflected power". And it shows that neither the transmitter nor the load see any changes in dissipation.

If I had chosen a different length line, then changing its Z0 would have changed the impedance seen by the transmitter, which would have changed its efficiency by an amount which could have been determined only with additional knowledge about its characteristics. But replacing the transmission line with a lumped impedance transforming network would have exactly the same effect on the transmitter, again illustrating that the only important factor is the impedance the transmitter sees and not the "reflected power" in the line it's connected to.

This posting is being made, though, for the benefit of other readers. I've explained this many times to you before with no noticeable effect on your understanding.

Cecil has used this fact as a convenient way of avoiding confrontation with the illustrations given in my "food for thought" essays. However, those models aren't claimed to be Thevenin equivalents of anything. They are just simple models consisting of an ideal source and a perfect resistance, as used in may circuit analysis textbooks to illustrate basic electrical circuit operation. The dissipation in the resistance is clearly not related to "reflected power", and the reflected power "theories" being promoted here fail to explain the relationship between the dissipation in the resistor and "reflected power". I contend that if an analytical method fails to correctly predict the dissipation in such a simple case, it can't be trusted to predict the dissipation in other cases, and has underlying logical flaws. For all the fluff about photons, optics, non-dissipative sources, and the like, I have yet to see an equation that relates the dissipation in the resistance in one of those painfully simple circuits to the "reflected power" in the transmission line it's connected to.

Thank you, that's exactly what I've tried to do. But calling all such simple circuits "Thevenin equivalents" is a convenient way to avoid having to explain the phenomena they illustrate. So that has been the tactic of some of the "reflected power" proponents.

In a previous life I was tasked with tailoring a large number of RG-58 cables connecting radar scopes at a new installation in Korea. This involved cutting the cables to length and installing clamp and solder type BNC connectors. The rumor was that the Korean troops were supposed to be helping us, but we never saw them -- until one day, when they showed up. The one assigned to help me sat down and, neither of us being fluent in the other's language, I proceeded to show him how to assemble the connector.

Now the job of one of the several pieces, a metal ring, is to push against and expand a rubber washer, which is mainly what holds the connector together. This piece looks like it should go upside down from the correct orientation, but if put on that way, the rubber washer won't expand and the connector will come off very easily, with only a gentle tug. If assembled correctly, it'll take a lot of pulling, as Sal says, to get it off. I've never seen a correctly assembled connector come off.

Getting back to the story, I carefully demonstrated the correct assembly method to the Korean troop, emphasizing the orientation of the ring. After putting the connector on, I showed him our standard test. We would grab the connector in one hand and about two feet down the cable with the other. Then we put our hands together, making a loop of cable, and briskly yanked them apart, resulting in a really good sharp tug on the connector. A properly assembled connector had no trouble with this test.

So I gave him the parts and went to work on a connector. After a while he handed me the cable with attached connector. I gave it the tug test and the connector snapped right off. So I repeated the mimed instructions, with extra emphasis on the ring orientation, then put him to work again and got back to what I was doing. When he was finished he handed me the connector, I did the yank test, and again the connector popped right off. He shrugged, muttered something under his breath, got up, and left. Guess he figured he'd had enough of that game, where he assembled connectors and I pulled them off. We never saw the Korean troops again.

Another story, but with a different outcome.

I worked in a training school at one stage, and we thought we would get trainees to make up BNC RG58 patch cables as a practical exercise, and we would feed the output into our satellite labs where cables didn't seem to last long (trainees pulled equipment trolleys around by the coax if it didn't reach the desired socket).

Total failure, the BNC field serviceable connectors were just too complicated for dissinterested trainees more interested in discussing fast cars than concentrating on the job... and they had no stake in it, if the cables didn't work, it didn't matter too much.

Solving the problem of the connectors pulling off led me to the Amphenol specs, and I found that the pull out spec for the field serviceable connectors was *much* lower than the spec for the crimp connectors.

So, I bought a quality crimp tool (in those days, it was a few hundred dollars), and some Kings crimp connectors, and we switched the classes to use the crimp components and a trim jig. The outcome was much better, fewer faulty cables, and the crimped cable retention was much better and consistently so.

No I know that one of the large suppliers to hams advertises "crimped, not soldered", but that is just a blatant case of playing to the market. A bit like the single core 4:1 Guanella balun that manufacturers attribute to Sevik's assurance that it will work fine on a fully floating load... whan antenna system is a fully floating load. The theme is the customer is always right, if he wants something that doesn't make sense, see Rule 1.

An interesting new connector type is the "compression connectors", "Snap-n-Seal" is a proprietary name. I tried some of these on RG6, and a bit suspicious of the cable retention mechanism, every one I tested using different types of RG6 (including QS), hung on until the cable tore apart some distance from the connector.

Got that back the front, didn't I.

DXE advertises "soldered, not crimped", but that is just a blatant case of
playing to the market.

2518. Re: Radials: Induced currents due to direction versus radiation pattern

Newsgroup: rec.radio.amateur.antenna
Date: 2010-06-15 21:32:26 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <6qadnbU3-OLzblrRnZ2dnUVZ_r-dnZ2d@giganews.com>
Source record: 8918

Some of the statements I've seen are based on assumptions that there is a large number of radials, or that the radials are evenly distributed. When either of those aren't true, some of the "conventional wisdom" doesn't apply.

I also need to point out that EZNEC isn't a very good tool for studying some of the effects of abbreviated radial systems.

It is possible to create a small amount of directivity by putting more radials in some directions than others. I'll use as an example an NEC-4 (which allows modeling buried conductors) model I had previously made of a 3.7 MHz quarter wavelength vertical with 60 radials buried in average ground. The radial length is 0.5 wavelength in free space, or about 2.25 wavelengths when buried, since the propagation velocity is much slower in the ground.

With all 60 radials, the maximum sky wave gain is 1.08 dBi at an elevation angle of 26 degrees. If you delete half the radials, the gain is 0.19 dBi at 27 degrees in the direction of the radials, and -1.39 dBi in the opposite direction. So about 1-1/2 dB of directivity has been accomplished, at the expense of about a dB of gain in the best direction.

As far as radiation from radials is concerned, a pair of opposed radials (that is, ones facing opposite directions) radiate very little because their fields nearly or completely cancel in all directions. The example antenna with only two opposing radials shows -3.57 dBi gain at 25 degrees elevation, and 0.3 dB or less deviation from having the same gain in all directions, at any elevation angle.

The same model with only one radial shows a front/back ratio of about 0.8 dB at the elevation angle of maximum gain, and about 1 dB at some higher angles, so even that doesn't give much directivity.

Analyzing antennas having radial systems with EZNEC requires elevating the radials above ground. When many radials are used, the approximation to a buried system isn't too bad, and the main limitation of the model (homogeneous ground) prevents highly accurate results anyway. But a single radial behaves much differently when buried than when elevated even just a little. Elevating the single buried (0.1 meter deep) radial of the previous example to 5 mm above ground results in about 5.6 dB front/back ratio and -7.74 dBi maximum gain vs -4.42 dBi with the radial buried. So if you want to get significant front/back with a single radial, keep it above the surface. Gain varies quite a bit with radial height and length.

EZNEC can be used to see what happens to the pattern and gain as one or more radials are elevated at various heights and made various lengths. The results can be quite surprising. While the homogeneous ground approximation makes it unlikely you'd see results matching a model at a particular height, the general effect of height can prove illuminating.

I saw the challenge and note the lack of response.

Let me offer a steady state solution.

In the case of a simple source being an ideal AC voltage generator of Vs and an ideal series resistance Rs of Ro, and that Zo=Ro, for any arbitrary load, at the source terminals, Vf=Vs/2, Vl=Vf+Vr=Vs/2+Vr, and the voltage difference across Rs is Vs/2-Vr (noting that Vr is a complex quantity and can have a magnitude from 0 to Vs/2 at any phase angle), therfore dissipation in Rs is given by:

Prs=(Vs/2-Vr)^2/Rs where Vs is the o/c source voltage, Vr is the complex reflected wave voltage equivalent, Rs is the source resistance.

Clearly, dissipation in Rs is related to Vr, but it is not simply proportional to the square of Vr as believed by many who lack the basics of linear circuit theory to come to a correct understanding.

Roy, is that a solution?

Owen

obviously its not the 'reflected power'... that can be easily
disproved by showing that the length of the line changes the impedance
seen at the source terminals without changing the power that was
reflected from the load. since it is the impedance at the source
terminals that determines the performance of the amp the power that is
reflected is irrelevant.

however, it should be relatively easy to derive such a relation for a
simple thevenin source with a lossless line and a given load
impedance... just transform the impedance along the length of the line
back to the source then calculate the resulting current or voltage

from the source. that would give you the power dissipated in the source. then you could also calculate the reflection coefficient and separate the forward and reflected waves... and if you did it all correctly and kept everything in terms of RL, Z0, and the length of the line you could come up with a family of parametric curves relating the power dissipated in the source resistance to the reflected power over a range of load impedances for a given line length, or for varying line length for a given load. obviously a purely academic exercise that should be left for a rainy day.

no, i've read enough thank you.

I think there are 2 basic things you are missing... V and I are functions not only of time, but of distance along the line, both for the forward and reflected waves. looking at them at specific points can lead to incorrect assumptions and over simplified conclusions. Also, there are very good reasons why the sinusoidal steady state condition is used to simplify the equations they way they are normally shown, and why your over simplifications won't hack it in the long run. to do the full analysis of a distributed system (except in very special cases) for an arbitrary waveform requires summations of reflections both ways on the line over many reflection periods.. the results of this for step functions can be seen with simple tdr's on lines with multiple discontinuities where you can see the reflections ringing down.

Tom, I understand the variation of the line-input impedance resulting from the change in length of the trombone line with the reflection coefficient of 0.01. However, I'm totally unaware of how the change in line-input impedance relates to a change of frequency of the forward wave of 100 Hz. Please explain.

Further, will you please also explain how the effect of the trombone exercise determines the value of the source impedance, which, for example, you stated is 56+j16 ohms? In other words, what mechanism produced that value ? Sorry, Tom, I'm a little dense on this issue.

Roy, unfortunately for your argument, the impedance seen by the
transmitter is:

Z = (Vfor + Vref) / (Ifor + Iref)

where the math is phasor math. ANY DEVIATION AWAY FROM THE Z0-MATCHED
LINE VALUE OF IMPEDANCE = Vfor/Ifor IS *CAUSED* BY THE REFLECTED WAVE!
Given that fact of physics, how can you possibly argue that the
reflected wave doesn't affect dissipation/damage at the transmitter???

The power density equation containing an interference term is what you need to use and I seriously doubt that, after 5+ years, you are ignorant of that equation. In your food-for-thought, forward/reflected power example, all you have to do is figure out the power in the forward wave and the power in the reflected wave at the source resistor and plug them into the following equation:

Ptot = P1 + P2 + 2*SQRT(P1*P2)*cos(A)

where 'A' is the angle between the forward voltage and reflected voltage. For instance, if the reflected voltage arrives back at the source resistor in phase with the forward voltage, cos(A) = cos(0) = 1 and there is constructive interference which increases the dissipation in the source resistor. If the reflected voltage arrives back at the source resistor 180 degrees out of phase with the forward voltage, cos(A) = cos(180) = -1 and there is destructive interference which decreases the dissipation in the source resistor. If the reflected voltage arrives back at the source resistor 90 degrees out of phase, cos(A) = cos(90) = 0, and there is no interference and all of the reflected power is dissipated in the source resistor. If you had ever read my energy article, published many years ago, you would know what effect superposition accompanied by interference can have on the redistribution of energy. But you instead said, "Gobbleygook" (sic) and plonked me. Time to pull your head out of the sand.

The above power density equation not only agrees with all of your power calculations, it tells anyone who desires to acquire the knowledge, exactly where the reflected energy goes and why it is not always dissipated in the source resistor.

Hello boys... good day to you. You are make me study so hard forgotten
stories, dusting off old books... First, I sorry for I lost some posts
(I miss free news servers, ISPs here, nones!). Thanks to Roy, Owen,

K1TTT, etc. I read them today.

(>: Please do not quarrel! :>). Someone said (I think it was Nikita Kruschev to the Pope, I am not sure) => "If we can not agree on heaven's things, let us at least agree on the earth's things...." :>)

Why not make a "truce" for a few hours with the "why's" to verify if the proposed methods arrives at the same numerical results in terms of PRs and Pl first with our minimalistic Vg and Rs? (for the sake of novice readers)

For not to work too much, calculations could be reduced to three resistive Zls, and three lengths of TL. Let me suggest 25, 50 and 100 ohms RLs and 0.5, 0.25 and 0.125 of lambda (to honor Cecil and Roy papers), Vg voltage = 100 V RMS, Rs 50 ohms, Zo obviously 50 ohms too (lossless line). Zl=50 ohms and 1/2 lambda TL are for beginners, as me ;>D

Miguel, I gave an expression for power in your simple source circuit in a recent post, did you see it. Well here it is again:

Prs=(Vs/2-Vr)^2/Rs where Vs is the o/c source voltage, Vr is the complex reflected wave voltage equivalent, Rs is the source resistance.

If the reflected wave was always, and entirely dissipated in Rs in that type of source, then Prs=Vr^2/Zo=Vr^2/Rs... but it isn't, see the above expression.

You can work one case, three cases, three x three cases, but they are not as complete as the expression above that shows that in the steady state, Prs is not simply equal to the 'reflected power'.

But if you want, work the cases and report the results here, it is a trivial exercise. You will accept the results more readily if you work it our yourself.

Owen

> Prs is not simply equal to the 'reflected power'.

I don't remember anyone saying that Prs is equal to the reflected power and of course it is not. What you guys are missing are the effects accompanying interference from superposition. There is another mechanism besides the reflection mechanism that can redistribute the reflected power. The power density equation includes an interference term that indicates what happens to the energy.

Prs = Pfor + Pref + 2*SQRT(Pfor*Pref)*cos(A)

This equation gives the same answer as your equation but it also indicates what happens to the energy components. A is the phase angle between Vfor and Vref. The last term is the *interference* term.

If the interference term is zero, there is no interference and all of the reflected power is dissipated in Rs.

If the interference term is negative, there exists destructive interference at Rs and power is redistributed toward the load as constructive interference. This is technically not a reflection although the results are the same as a reflection.

If the interference term is positive, there exists constructive interference at Rs and excess power is dissipated in Rs.

Let's look at your equation, Prs=(Vs/2-Vr)^2/Rs

Vfor = Vs/2, so Prs = (Vfor+Vref)^2/Rs (phasor addition)

Prs = Vfor^2/Rs + Vref^2/Rs + 2*Vfor*Vref*cos(A)/Rs

Prs = Pfor + Pref + 2*SQRT(Pfor*Pref)*cos(A)

I just derived the power density equation (with its interference term) from your equation. The power density equation reveals the interference term which tells us exactly where the reflected power goes.

I learned about destructive and constructive interference at Texas A&M in the 1950s.

> me ;>D

Miguel, Owen's equation, Prs=(Vs/2-Vr)^2/Rs, and the following power density equation are equivalent and yield the same answers for Prs. However, the power density equation indicates the magnitude of interference present at Rs and the sign of the interference indicates whether the interference is destructive or constructive. This general equation is how optical physicists track the power density in their light and laser beams.

Ptot = P1 + P2 + 2*SQRT(P1*P2)*cos(A)

where A is the phase angle between the electric fields of wave1 and wave2. In our case, it will be the phase angle between the forward wave and the reflected wave at the source resistor.

For our purposes, based on your specifications, we can rewrite the equation:

Prs = Pfor + Pref + 2*SQRT(Pfor*Pref)*cos(A)

Pfor is fixed at 50 watts. For a 50 ohm load, Pref=0.
For a 25 ohm or 100 ohm load, Pref=5.556 watts.
Angle A is either 0, 90, or 180 degrees depending upon which example is being examined.

For all three of the RL=50 ohm examples, Pref=0, the line is matched and Prs = Prl = 50 watts. There is no question of where the reflected power goes because Pref=0.

For all three of the 0.125WL examples, since A=90 deg, the interference term in the power density equation is zero so for the 25 ohm and 100 ohm loads:

Prs = Pfor + Pref = 55.556 watts

When there is no interference, all the reflected power is obviously dissipated in the source resistor. This matches my "zero interference" article.

For all four of the other examples, the SWR is 2:1.
Pfor = 50w, Pref = 5.556w, Pload = 44.444w

If the reflected wave arrives with the electric field in phase with
the forward wave,
angle A = 0 degrees so cos(A) = +1.0
The positive sign tells us that the interference is constructive.

Prs = Pfor + Pref + 2*SQRT(Pfor*Pref)*cos(A)

Prs = 50 + 5.556 + 2*SQRT(50*5.556)

Prs = 55.556 + 33.333 = 88.89 watts

In addition to the sum of the forward power and reflected power being
dissipated in Rs, the source is forced to supply the additional power
contained in the 33.333 watt constructive interference term.

So Psource = 100w + 33.333w = 133.33w

Because of the constructive interference, the source not only must
supply the 100 watts that it supplies during matched line conditions,
but it must also supply the constructive interference power of 33.333
watts.

When the reflected wave arrives at Rs 180 degrees out of phase with
the forward wave,
cos(A) = cos(180) = -1.0. The negative sign indicates that the
interference is destructive.

Prs = 50 + 5.556 - 2*SQRT(50*5.556)

Prs = 55.556 - 33.333 = 22.223 watts

The source is forced to throttle back on its power output by an amount
equal to the destructive interference power of 33.33 watts. It is
supplying the 22.223w dissipated in Rs plus the difference in the
forward power and the reflected power.

Psource = Prs + Pfor - Pref = 66.667w

Note that the source is no longer supplying the reflected power. The
destructive interference has apparently redistributed the incident
reflected energy back toward the load as part of the forward wave.

In attempted chart form, here are the Prs values:

line length, 0.5WL, 0.25WL, 0.125WL

25 ohm load, 88.889w, 22.223w, 55.556w

50 ohm load, 50w, 50w, 50w

100 ohm load, 22.223w, 88.889w, 55.556w

Thinking about this some more, it should say:

Clearly, dissipation in Rs is related to Vr, but the contribution due to Vr
is not simply Vr^2/Rs as believed by many who lack the basics of linear
circuit theory to come to a correct understanding.

I see all kinds of crazy matching sections in posts about 6 meter beams. How about direct connect. I have an A4S that has major issues in the traps and I cant find the problem (IE I opened them and cant find anything) SOOO I have a new A4S coming.

Has anyone taken an old 3 elem tribander and converted it to 6 meter monobander using the direct connect.

Any Issues.

Would a 4 elem be better since its a long boom ?

I'm pretty sure I know the answers. Just want to confirm and see if there is any reason not to direct connect rather than through a hairpin or a gamma match.

To deal properly with the fact that Vr has magnitude and phase, the above
should we written as:

Prs=|(Vs/2-Vr)|^2/Rs where Vs is the o/c source voltage, Vr is the
complex reflected wave voltage equivalent, Rs is the source resistance.

If the reflected wave was always, and entirely dissipated in Rs in that
type of source, then Prs=a+|Vr|^2/Zo=a+|Vr|^2/Rs (where a is some
constant value)... but it isn't, see the above expression.

Again, a straw man. To the best of my knowledge, nobody has said that
reflected power is "entirely dissipated in Rs" (except for the special
case when interference doesn't exist.)

If you have a typical attic (inverted V) why not build your own. For a scanner you probably wouldn't notice any difference between it and a commercial one.

A guy I know used a bicycle wheel for the top hat and wires for the cone. He also reckons that its a reasonable match on two as well.

Sorry, I don't think so. The very first equation, Vf=Vs/2, would be true only if the load = Ro or for the time between system start and when the first reflection returns. For the specified steady state and arbitrary load, Vf would be a function of the impedance seen by the source which is in turn a function of the line length and load impedance.

I'm not saying an equation relating "reflected power" and source dissipation can't be written, but it does involve load impedance and line length and Z0. (Equations written with Vf and Vr as variables tend to conceal the inevitable dependence of these on line length and Z0 and load impedance, but the dependence is still there.) And the equation will show that there isn't any one-to-one correspondence between the two quantities. For a given source voltage and resistance, the source resistance dissipation depends only on the impedance seen by the source. This in turn depends on the length and Z0 of the line and the load impedance, and can be created by an infinite combination of loads and lines having different "reflected powers". As I illustrated in an earlier posting, a constant load with various lines having very different "reflected powers" can present the same impedance to the source and therefore result in the same source resistor dissipation.

Likewise, different lines having the same "reflected powers" can result in different impedances seen by the source and therefore different dissipations. So the two aren't really related, even though you could write an equation which contains both terms.

Vf means the 'forward wave' voltage equivalent voltage at the source
terminals.

I provide the mathematical development of the case that Vf=Vs/2 where
Rs=Ro=Zo at http://vk1od.net/blog/?p=1028 .

Can you fault that development?

> --
> 73, Cecil, w5dxp.com

lets see one case off the top of my head... 100 ohms resistive at 1/4 wave, transformed back to the source results in 25 ohms, pure resistive. 50 ohm source in series with 25 ohm transformed load gives 100v/75ohms = 1.333A from at the source terminals and 100v*25ohm/(25ohm +50ohm) = 33.33V. power from the source has to equal power into the load since the line is lossless so PL = 33.33v*1.333a = 44.44w. power dissipated in the source resistor =1.333a*(100v-33.33v)=88.88w

no sines, no cosines, no square roots, no Pfor/Pref... so much simpler using voltage or current and simple transformations.

I would really like to see you prove that assertion.
If Rs = 50 ohms and Z0 = 50 ohms, why would the reflected wave change
the forward power since the reflected wave sees a matched 50 ohm
"load"? Hint: The forward power won't change unless there is a re-
reflection at the source. You have deliberately designed your food-for-
thought example to avoid re-reflections at the source. Lumped-circuit
models seem to have atrophied a lot of brains.

Those are the kind of strange concepts that result from over-
simplification of the math models. When one denies the ExH energy
content of an EM wave (even a reflection) one chooses to follow
oneself down a primrose path. Optical physicists can track their light
wave energy down to the last photon. Why are some RF engineers so
ignorant in the tracking of energy that they assert there is no energy
in a reflected wave?

would you care to provide us with the general equation for A given a complex load impedance and a line length other than a multiple of 90 degrees?

Yes, but determining where the reflected energy goes is the title of
this thread. My method shows where the reflected energy goes and yours
does not! That's the entire point.

It's simply the relative phase angle between the forward voltage and
reflected voltage at the source resistor. I trust that you can manage
that without my help.

ah, but it does... it gives the exact same results but without all the
power manipulations. the point is, in sinusoidal steady state you can
calculate the impedance seen by the source and get all those same
results much simpler than trying to track forward and reflected
powers. and if you really want to know the source and load powers
they are easy enough to get as i showed.

ah, so you do have to calculate the voltages, which would requires two
transformations of the length of the coax plus calculating the
magnitude and angle of the complex reflection coefficient then adding
them all up. still sounds like more work than necessary.

Hello all

If I do not make any mistake, my numbers agree with yours Cecil, it is
a pleasure (my procedure was the old plain and simple standard) :>)
I know, 1000 examples probe nothing, only one popperianists man can
bring a black swan at any time and falsify the induction :>). but now
seems more clear to me you have a predictive model that render
identical numbers of my classical one, at least in basic tests, it is
a step forward to better considerate your efforts and with goodwill
begin to establish basic points of agreement.
I recognize it is a more simple approach the classic method (as said
K1TTT) to me too, but also I think not always one good method or model
it is more convenient to understand another useful view of phenomena.
Phasorial solutions are good, practical and likely complete electric
solutions but in my opinion they do not married very well with other
more general electromagnetic and physics models (wave guides perhaps?
I have not experience); unification has its advantages too (However my
favourite answer was definitely the Roy's one in the fourth post of
the thread, hi hi...)

73 - Miguel - LU6ETJ

PS: Owen do not be upset with me :>) most of my available newsgroup
time it is spent in translate to english without flaws that may induce
to misinterpretations (all of you are very demanding with precise

wording and exact definitions), one mistake and I will need three or four painly translations more to clarify :>D

Today I tested your interesting formula with a Half wave 50 ohms TL, loaded with 100 and 25 ohms respectively. Vs=100 Vrms, Rs=50 ohm give 2:1 VSWR. In both cases then Pf 50 W, Pr=5.5 W, Pnet=44.4 W. Giving Vf=50 V and Vr=16,6 V aprox. for both loads.
I am using (Pf=Pnet / (1-Rho^2) and Pr=Pnet / ((1/1/Rho^2) -1) formula which not gives different sign to Vr, in such case applying to PRs=(((Vs/2)-Vr)^2)/Rs => ((50/2)-16.66)^2/50. I get PRs=22,2 with both loads because the sign of Vf (always +) from simple Pr and Pf formulas, changing the sign of Pr render Rs=88,8 W for Prs (OK).

I have in my disk a very descriptive, advisable and friendly article downloaded from:
http://www.ittc.ku.edu/~jstiles/622/handouts/Transmission_Lines_package.pdf

In page number 88 there is a agreement with your formula in "Is zo of aa HF ham tx typycally 50+j0?".

I stand corrected. In the special case of Rs = Z0, the steady state forward voltage and therefore "forward power" become independent of the transmission line length and load impedance, just as you said and show in your analysis.

But this isn't true in the general case where Rs isn't equal to Z0. In the general case, the forward voltage is

Vf = Vfi * exp(-j*theta) / (1 - Gs*Gl*exp(-j*2*thetal))

where Gs = reflection coefficient at the source looking back from the line = (Zs - Z0)/(Zs + Z0)
Gl = reflection coefficient at the load = (Zl - Z0)/(Zl + Z0)
theta = distance along the line from the source end
thetal = length of the line in radians
Vfi = initial forward voltage = Vs * Z0 / (Zs + Z0)

At the input end of the line, theta = 0 so

Vf1 = Vfi / (1 - Gs*Gl*exp(-j*2*thetal))

and the reverse voltage at the input is

Vr1 = Gl * Vf1 * exp(-j*2*thetal)

Note that although Vf is a function of Gs, reflected voltage Vr is also a function of Gs and their ratio is not. So VSWR and Pf/Pr don't depend on Gs. But the general equation for Vf does include line length and Z0 as well as both source and load Z.

In the example I posted earlier (Transmitter power 100 watts, load Z = 50 + j0, line length 1/2 wavelength), no mention was made of the source impedance, only the power being delivered by the transmitter, which was the same for both cases since the impedance seen by the transmitter didn't change. In the first case, where Z0 = Zl = 50 + j0, the forward power on the line was 100 watts and reverse power was zero. In the second case, the line Z0 was changed to 200 ohms. This caused an increase in forward power to 156.25 watts (calculated from VSWR). From these we can infer that the forward voltage increased by a factor of 2.5 from sqrt(100 * 50) = 70.71 Vrms to sqrt(156.25 * 200) = 176.8 Vrms. Let's see if this agrees with the equations.

When the line is a half wavelength long, thetal = pi, so the equation for Vf1 simplifies to:

Vf1 (half wavelength line) = Vfi / (1 - Gs*Gl)

Expanding Vfi, Gs, and Gl results in

Vf1 (half wavelength line) = Vs * (Z0 + Zl)/(2 * (Zs + Zl))

Various combinations of Vs and Zs can give us the 100 assumed watts, but we don't need to specify any specific values. Leaving Vs and Zs as unknown constants and Zl as fixed, we can find the ratio for two different values of Z0:

Vf1 = Vs * (Z01 + Zl)/(2 * (Zs + Zl))
Vf2 = Vs * (Z02 + Zl)/(2 * (Zs + Zl))

Vf2/Vf1 = (Z02 + Zl)/(Z01 + Zl)

In the example, case 1 had Z0 = Z01 = 50; case 2 had Z0 = Z02 = 200, and Zl was 50 for both. So Vf2/Vf1 = (200 + 50)/(50 + 50) = 2.5, which agrees with the calculation based on VSWR.

Once again, the general equations for Vf and Vr and therefore Pf and Pr include Zs, Zl, line length, and line Z0. While one or more of these terms might disappear in special cases or ratios, they all have to appear in any equation of general applicability.

> Vf=50 V and Vr=16,6 V aprox. for both loads.

I posted a correction to the formula to properly account for the fact
that Vr is a complex quantity.

The corrected expression is Prs=|(Vs/2-Vr)|^2/Rs . Apologies if you
missed it. Of course, the V quantities are RMS, it is a bit of a botch of
RMS with phase as we often do in thinking... but I see you using the same
shorthand in your calcs. Although we are using RMS values, don't overlook
that where they add (eg Vf+Vr) you must properly account for the phase.

For your cases:

For the 25+j0 load, Vr=-16.67+j0, so Prs=|50--16.67|^2/50=88.9W.

For the 100+j0 load, Vr=16.67+j0, so Prs=|50-16.67|^2/50=22.2W.

Of course, for a 50+j0 load, Vr=0, so Prs=|50-0|^2/50=50.0W.

As you can see, the first two cases have the same |Vr| (though different
phase), the same 'reflected power', and yet Prs is very different.

Consider an extreme case, Zl=1e6, VSWR is extreme, almost infinity, Vref=
50+j0, so Prs=|50-50|^2/50=0.0W. Here, your 'reflected power' is as large
as it gets, but the power dissipated in the source is zero.

The notion that reflected power is simply and always absorbed in the real
source resistance is quite wrong. Sure you can build special cases where
that might happen, but there is more to it. Thinking of the reflected
wave as 'reflected power' leads to some of the misconception.

Thanks Roy.

There may have been some misunderstanding. I thought your challenge was
issued in the context of the ideal 50 ohm source that Miguel was using as
a test case.

The maths for the ideal 50 ohm source test case is so simple, that it is
evident the |Vr|^2/Ro is not simply summed into Rs's dissipation.

Of course, in the general case, the maths is uglier, but since the
special case of Rs=Ro=Zo proves the 'reflected power' is not simply
dissipated in Rs, it (the general case) must give the same outcome.

The above equations are used in a directional wattmeter.

You have made some arithmetic errors below. I have re-arranged
your prose a bit to allow correction, then comment.

> well, maybe i missed something... lets look at the voltages:
>

> Vf(t)=(100+50*2)/2 = 100
> Vr(t)=(100-50*2)/2 = 0

You made a substitution error here. On the transmission line
with a constant DC voltage:
V(t)=100V
I(t)=0A

substituting in to
Vf(t)=(V(t)+R0*I(t))/2
Vr(t)=(V(t)-R0*I(t))/2

yields
Vf(t)=50V
Vr(t)=50V

and
If(t) = 50/50 = 1a
Ir(t) = 50/50 = 1a

Recalling that the definition of forward and reflected is
V(t)=Vf(t)+Vr(t)
I(t)=If(t)-Ir(t)
we can check our arithmetic
V(t)= 50+50 = 100V
I(t)= 1-1 = 0A
Exactly as measured.

If you are disagree with the results, please point out
my error in the definitions, derivations or arithmetic.

If you agree with the results, continue reading.

> so there is a reflected 2a current you say?

Well, with no arithmetic errors it is 1A of forward and
reflected current.

> where does that go when it gets back to the source?
> we know that when the 100v source is open
> circuited as it must be in this case that it develops 100v across its

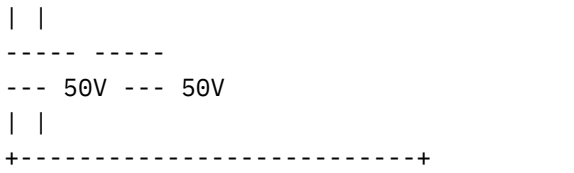
> the source. it can't be reflected since the source impedance matches
> the line impedance. so where does it go? maybe those simple
> algebraic expressions have to be reconsidered a bit.

Now you see the problem of assigning to much reality to the
these waves.

In principal, the derivation and use of forward and reflected
waves is no different than using superposition to compute the
currents and voltages in simple circuits. Consider
50ohms
+----------\/\/\/\/---------+



Obviously the current in the resistor is 0, but let us
use superposition to solve this problem.

To solve using superposition, one sets all but one of the
voltage sources to zero and then computes the currents. Repeat
for all voltage sources and sum the results in each element.

So set the right voltage source to zero.
The current through R is 1A.
Set the left voltage source to zero.
The current through R is −1A.
Total current through R is 0A, as expected.

Asking “where did the reflected current go?” on the transmission
line case is like asking “where did the −1A go?”. The question
is nonsensical. The −1A is simply an intermediate result in a
method that lets the problem be solved.

The fallacy of assigning powers to the reflected waves also
has an analog in the simple circuit above.
Using the currents derived above, compute the power from the
left source.
50*1*1 = 50W
and the right source
50*(-1)*(-1) = 50W
So what do your think...
Should we add them to get 100W?
Subtract them to get 0W?
Or is the operation invalid because superposing power just
does not work?

Answer 3 is correct.

Taking this knowledge back to transmission lines, the surprise
is that subtracting reflected power from forward power actually
yields the net energy flowing. How can that be?

By substitution, it is easy to show that the rules used to
derive Vf and Vr results in
P(t)=Pf(t)-Pr(t)

So, while superposing powers, does not work in general, it does
for this case. Directional wattmeters take advantage of this
ideosyncracy to let the user compute the power being delivered
to the load.

None-the-less, thinking of these waves as transporting energy
will lead to much confusion.

...Keith

Ahhh. Your standard answer. You are an RF dude and there is nothing
that can possibly be learned from simple DC circuits.
Especially when the results challenge your beliefs.

Still, I observe that you have discovered no errors in the exposition.
Which is good.

We studied DC circuits in EE101. Later we were forced to expand our
knowledge into distributed networks because the DC circuit model
failed at RF frequencies.

> Still, I observe that you have discovered no errors in the exposition.

I have not wasted my time time trying to discover any errors. In a
nutshell, what new knowledge have you presented?

Again, exactly who proposed that notion? The "power" in a reflected wave is actually reflected energy measured at some point on the transmission line. Reflected EM waves cannot exist without ExH energy per unit time per unit area.

The special case where 100% of the reflected power incident from a Z0=50 ohm transmission line is dissipated in the 50 ohm source resistor happens when there is zero interference between the forward wave and reflected wave. Since it is not true when interference exists, it is logical to conclude that interference has something to do with the reflected power results deviating from the zero interference case - and so it does. The interference term in the power density equation indicates what kind of interference exists and what happens to the interference energy.

Roy's experiment was designed to eliminate re-reflections from the source and it does exactly that. What that means is that all of the variations in power distribution are associated with interference, the other mechanism by which RF wave energy can be redistributed. Contrary to w7el's assumption, EM wave reflection is NOT the only mechanism for redistributing RF energy in a transmission line. That glaring fact of physics is what most of the RF experts are missing.

> If I do not make any mistake, my numbers agree with yours Cecil, it is
> a pleasure (my procedure was the old plain and simple standard) :>)

If, instead of a voltage analysis, one does an energy analysis, what happens to the reflected energy becomes obvious. I posted an earlier example that nobody solved. So let me repeat it here.

------Z01------+------Z02------

The power reflection coefficient at point '+' is
rho^2 = 0.5. The power transmission coefficient
is (1-rho^2) = 0.5
Pfor1 on the Z01 line is 100w
Pref1 on the Z01 line is 0w
What are Pfor2 and Pref2 on the Z02 line?
What is the SWR on the Z02 line?

The power reflected back toward the source at point '+' is

Pfor1(rho^2) = 100(0.5) = 50w

We know that Pref1 is zero, so

Pref2(1-rho^2) = 50w

Since 1-rho^2 is 0.5, Pref2 must be 100w and

Pref2(rho^2) = 50w

We also know that Pfor1(1-rho^2) = 50w

So we have two 50w waves trying to flow toward the source and two 50w waves trying to flow toward the load. Do we have 100 watts flowing in both directions? No, that would be superposition of power which is a no-no. Using the power density equation indicates what is happening.

Pref1 = 0 = Pfor1(rho^2) + Pref2(1-rho^2) minus total destructive interference at the Z0-match

Pref1 = 50 + 50 - 2*SQRT(50*50) = 0

Pfor2 = Pfor1(1-rho^2) + Pref2(rho^2) plus total constructive interference

Pfor2 = 50 + 50 + 2*SQRT(50*50) = 200w

Since Pref2/Pfor2 = 0.5, the SWR on the Z02 line is 5.83:1

Note that we have solved the problem without knowing the value of Vfor1, Vfor2, and Vref2. But let's assume Z01 is 50 ohms which makes Z02 equal to 291.5 ohms. Now we can calculate the voltages assuming Vfor1 at '+' is our phase reference:

Vfor1 = 70.7 volts at zero degrees at '+'
Vref1 = 0
Vfor2 = 241.4 volts at zero degrees at '+'
Vref2 = 170.7 volts at 180 deg at '+'

Vfor1(rho1) = 50v at zero deg
Vref2(tau2) = 50v at 180 deg

Vfor1(tau1) = 120.7v at zero deg
Vref2(rho2) = 120.7v at zero deg

There's the interference, voltage style. Two voltages superpose to zero toward the source while engaged in total destructive interference. What happens to the energy components that are supporting those two voltages? There's only one thing that can happen. They are obviously not flowing in their original directions so they must necessarily flow in the only other direction possible. Total destructive interference toward the source results in total constructive interference toward the load.

Someone earlier remarked about the fact that when two 50w waves combine, the result is one 200w wave. That is total constructive interference in action and that extra energy had to come from somewhere.

I have an old Radio Shack 11 meter 3 element beam that I plan to put on 6 meters. I once did the EZNEC modeling with the boom length being the only constraint. It was possible to come up with a model that would work with a direct match for 50 ohms to the driven element. I hope to try to construct it soon.

The problem with holding a few parameters constant is that you have to accept whatever gain, patterns and such that come with the deal.

I also have a very old Mosley 15 meter 3 element beam that I want to modify to 17 meters. I am having a lot of fun with PSK31 there with poor antenna setup now.

Tower space is a limiting factor in my case and I am not interested in anything that compromises my A3S!

I wish you were close to me rather than 2306.9 miles, I am looking for an old bargain tri band to tinker with. There is a lot there I don't understand!

Well I did find plans for a 6 elem on a 17.5ft boom. The boom on the
old A4S is 18Ft. If I use the parts off my old A3
and my A4 I should be able to come up with all the parts for the 6
element. And its direct connect.

I wonder how far above the A4 the 6 meter needs to be. I only have a
5ft mast.

my DX800 rotor should handle it.

And it works only if Z0 is purely real. When it's not, P(t) also includes Vf*Ir and Vr*If terms which are neither "forward" nor "reverse" power. It's unfortunate in a way that Z0 is close enough to being real for decent lines at Amateur frequencies that these terms are small. Otherwise they'd have to be confronted and some mistaken assumptions abandoned.

While Zo of transmission lines might not be purely real, if the sampler element is calibrated for V/I being real, then the power is given by 'forward power' - 'reflected power'. This is true even if the calibration impedance is different to the transmission line in which the measurements are made, though significant departure will impact measurement uncertainty.

For example, if I insert a 50 ohm Bird 43 in a 75 ohm line at 1.8MHz, and measure Pf=150W and Pr=50W, then the power is 150-50=100W. The insertion VSWR due to the Bird 43 is trivial in this case, so it hardly disturbs the thing being measured. Each of the power measurements is of little value alone, no inference can be made (in this case) of the actual line VSWR, but the difference of the Pf and Pr readings does give the power at that point.

I discuss this in my article entitled "http://vk1od.net/blog/?p=1004" at http://vk1od.net/blog/?p=1004 .

Good day:

> wave as 'reflected power' leads to some of the misconception.

Ugh! The slippery word again...! Please Owen, remember me what power
definition are you using here and expand the sentence idea.

> EM waves cannot exist without ExH energy per unit time per
> unit area.

This is what teachers taught me, but when the EM TL waves reachs a
"target" seems the issue arise in the newsgroup.
Puzzle to me why we can (want? :>)) not reconcile those physics

concepts with usual electricity concepts if today they arise from the same place ultimately?
Certainly in electromagnetism we deal with vectors E,D,B,H,S and in electricity with scalars V(t), I(t) or phasors, this is for convenience and simplicity, but I accept we should be able to understand them in both forms without contradiction.

Adding a directional wattmeter to the mix raises an interesting issue.

Recalling my earlier example of a 100 watt transmitter connected to a half wavelength 200 ohm transmission line and then to a 50 ohm resistive load, the "forward power" on the line was 156.25 watts and the "reverse power" or "reflected power" 56.25 watts. The subject of this topic asks where the "reflected energy" goes. Does it go back into the transmitter? Well, let's put a 50 ohm directional wattmeter between the transmitter and the line. It measures 100 watts forward and 0 watts reverse. So what happened to the "reverse power" on the transmission line? If it was going back into the transmitter, we've now fixed the problem just by adding the wattmeter. In fact, we could replace the wattmeter with a piece of 50 ohm transmission line of any length, as short or long as we want, and the "forward power" on that line will be 100 watts and "reverse power" zero. So we've protected the transmitter from this horrible, damaging "reverse power" just by adding a couple of inches of 50 ohm line -- or a directional wattmeter. Is this cool or what?

Or we can put the wattmeter at the far end of the line and read 100 watts forward and zero watts reverse, eliminating "reverse power" at the load -- although we've lost 56.25 watts of "forward power". Or put it at the center of the line, where we'd read a whopping 451.6 watts forward and 351.6 reverse(*).

These are the "forward power" and "reverse power" on the short 50 ohm transmission line (or lumped equivalent) inside the wattmeter. So we can create "forward power" and "reverse power" just by moving the wattmeter around. And most importantly, we can use it to isolate the transmitter from that bad "reverse power". What a powerful tool!

I should point out that the example doesn't even mention, or need to mention, the transmitter output impedance. The entire analysis holds for any transmitter impedance, whether "dissipative", "non-dissipative", linear, or nonlinear. Wherever the "forward power" and "reverse power" come from and do to, it doesn't depend on any particular value or kind of transmitter impedance.

(*) This brings up a great idea. Drop down to Radio Shack or HRO and pick up one of those circulator things that separates forward and reverse power. Put it into the middle of the line where you have 451.6 watts of "forward power" and 351.6 watts of "reverse power". Take the 351.6 watts of "reverse power", rectify it, send it to an inverter, and use it to run the transmitter -- you'll have plenty, even with poor efficiency, and you can unplug the transmitter from the mains. There should even be enough power left over to run your cooler and keep a six-pack cold. Then work DX with your 451.6 watts of forward power while you enjoy a cool one. Goodbye to electric bills! Hello to DX, free power, and a tall cool one!

except i can measure If and Ir separately and can see they are both
zero. this is where your argument about putting a resistor between
two batteries falls apart... there is a length of cable with a finite
time delay in the picture here. so it is possible to actually watch
the waves reflect back and forth and see what really happens. in the
case where the line is open at the far end we can measure the voltage
at both ends of the line and see the constant 100v, so where is the
voltage difference needed to support the forward and reverse current

waves? you can't have current without a voltage difference. plus i can substitute in a lossy line and measure the line heating and measure no i^2r loss that would exist if there were currents flowing in the line, so there are none.

try this case, which is something we do at work... take a 14ga piece of copper wire maybe 50' above ground, its characteristic impedance is probably a few hundred ohms, and put 100kv on it... how much power is it dissipating from your If and Ir heating losses?? lets say 200 ohms and 100kv gives 100,000/200a=500a, shouldn't take long to burn up that wire should it? and yet it never does... so why doesn't it have your circulating currents?

but you have already admitted that it is the only mechanism... though
you will now undoubtedly argue against yourself. em wave reflection
IS the only mechanism for redistributing rf energy, you admitted that
when you agreed that superposition of the waves is the mechanism that
causes the interference in the first place. since interference is
caused by superposition then wave cancelation and this so called
redistribution of energy is also caused by the superposition of the
reflected wave with the incident wave. RF experts are not missing
anything, they just don't talk in your fancy energy and power terms
all the time or figure how to calculate power superpositions... read
the 500 pages BEFORE the s-parameter discussion in your version of the

fields and waves book and learn the simple way to handle the single wave components that makes all that stuff you preach look over complicated.

except for the one guy in the other thread that likes his dc 'waves' i think most everyone else gets the same answers but won't acknowledge that the other peoples methods also work. even my simple transformed impedance method shows the same results, you just have to look at what it really means. the whole key is that it doesn't really matter, we know how to use voltage/current, E/H, powers, s-parameters, etc to design circuits, and as long as we know their limitations and stay within them everything should work the same way no matter how its designed on paper.

> Adding a directional wattmeter to the mix raises an interesting issue.

Roy,

I suspect that the directional wattmeter is in a large part responsible to the strong committment to the view the Pf and Pr are separate tangible quantities, and that they can be dealt with independently.

You will recall a raging argument some years ago about the possible range of rho, and insistence by some practical practitioners that rho could never be greater than unity because it would mean that reflected power was greater than forward power, obviously impossible, then citing experience with a directional wattmeter (calibrated for V/I being purely real) as evidence. Of course, telephony line designers know about this effect and do not have directional wattmeters to confuse their thinking.

You example goes on to point out the absurdity of application of that kind of thinking.

Miguel has asked why I keep quoting the term 'reflected power' etc, it is because it is a deceptive label that misrepresents the quantity.

Roy has explained, and I have explained in the articles I referenced, the assumptions that underly the concept that Pf=Vf*If, and its limitations.

There are many ham texts and articles that try to explain some concepts and deliver to the user a language and model that encourages extension to invalid application.

Miguel, in a steady state scenario with a source at one end of a TEM line and a load at the other, the power (rate of flow of energy) at any point is given by the product of instantaneous voltage and current. This is a time varying quantity which can be integrated over time to obtain the average power. At some points on the line, the instantaneous power may be negative for some parts of the cycle, which indicates that over a cycle, some energy is exchanged to and fro across that point, but the average power will always be from source to load, and that quantity will decrease from source to load as accounted for by line loss elements, though in the general case, not purely exponentially as sometimes believed.

Superposition and reflection are NOT the same mechanism. You are totally confused about what I have said. Wave REFLECTION (of one wave) is not caused by SUPERPOSITION (of two waves) and vice versa. Wave reflection happens to a single wave when it encounters an impedance discontinuity. Superposition requires two or more waves. They are clearly two completely different mechanisms. So I will repeat what I said before:

There are two mechanisms for redistributing the reflected energy back toward the load.

1. The re-reflection of the SINGLE reflected wave from the load at an impedance discontinuity associated with the power reflection coefficient, e.g. 0.5 in my earlier example. Thus in that earlier example, 1/2 of the reflected energy from the load is re-reflected back toward the load and joins the forward wave toward the load. That leaves 1/2 of the reflected energy that is transmitted through the impedance discontinuity toward the source without being reflected.

The second energy redistribution mechanism occurs associated with superposition of MULTIPLE WAVES.

2. The percentage of the reflected energy from the load that is transmitted through the impedance discontinuity toward the source superposes with the reflection of the source forward wave from the impedance discontinuity. In my earlier example, the following two wavefronts superpose in the direction of the source.

Pfor1(rho^2) = 50w and Pref2(1-rho^2) = 50w

Pref1 = 50w + 50w - 2*SQRT(50w*50w) = 0

This is the second mechanism (wave cancellation) that redistributes the energy in the canceled wavefronts back toward the load. This step 2 is technically NOT a reflection since it involves two waves. This is the step that the RF gurus are missing.

I really wish you understood the s-parameter equations which are easier to discuss than the above RF equations.

In the s-parameter equation:

b2 = s21*a1 + s22*a2

the term, s22*a2, is the SINGLE WAVE re-reflection term, i.e. a2 is
the reflected voltage from the load.

In the other s-parameter equation:

b1 = s11*a1 + s12*a2 = 0

s11*a1 and s12*a2 are the TWO WAVEFRONTS that superpose to zero, i.e.
engage in wave cancellation.

The subject of this thread is: "Where does it go? (mismatched power)".
So it did matter to the original poster. I have answered the question
by presenting the facts of EM wave physics known from the field of
optics. So now you say, "it doesn't really matter". That seems to be a
final fallback position.

> power" or "reflected power" 56.25 watts. The subject of this topic asks
> where the "reflected energy" goes. Does it go back into the transmitter?

------Z01=50------+------Z02=200------load

Pfor1 = 100w, Pref1 = 0w
Pfor2 = 156.25w, Pref2 = 56.25w
rho^2 = 0.36, rho = 0.6

That's obviously a Z0-match to 50 ohms. There are, as usual, four
wavefront components:

Pfor1(rho^2) = 36w, the amount of forward power on the 50 ohm line
that is reflected back toward the source.

Pfor1(1-rho^2) = 64w, the amount of forward power on the 50 ohm line
that is transmitted through the impedance discontinuity toward the
load.

Pref2(rho^2) = 20.25w, the amount of reflected power on the 200 ohm
line that is re-reflected back toward the load by the impedance
discontinuity.

Pref2(1-rho^2) = 36w, the amount of reflected power on the 200 ohm
line that is transmitted through the impedance discontinuity toward
the source.

Pref1 = Pfor1(rho^2) + Pref2(1-rho^2) - total destructive interference

Pref1 = 36w + 36w - 2*SQRT(36w*36w) = 0

Pfor2 = Pfor1(1-rho^2) + Pref2(rho^2) + constructive interference

Pfor2 = 64w + 20.25w + 2*SQRT(64w*20.25w)

Pfor2 = 64w + 20.25w + 72w = 156.25w

Note that the 72 watts of total destructive interference energy toward
the source has changed directions and joined the forward wave toward
the load as constructive interference.

No need to haul out a wattmeter or SWR meter. A pencil, paper, and
calculator is all one needs PLUS an understanding of the rules of
physics governing energy flow at a Z0-match.

Actually, you didn't even need to tell me what the Pfor2 and Pref2 values are. As you can see from the calculations, they are easy to calculate even when they are unknown.

How would you measure them? The standard definition of forward
and reflected waves are as I provided above. I suppose you could
construct your own definitions, but such a new definition would
be confusing and unlikely to have the nice properties of the
standard definitions.

> this is where your argument about putting a resistor between

> waves?

Well, as I suggested, the forward and reflected wave are somewhat
fictitious. They are very useful as intermediate results in solving
problems but, as you note above, quite problematic if one starts
to assign too much reality to them.

That is why they are quite analogous to the two currents in the two
battery example.

> you can't have current without a voltage difference.

You can, though, have an arbitrary current as an intermediate
result in solving a problem. With the two battery example, reduce
the resistor to 0 and an infinitely large current is computed in
both directions, though we know in reality that no current is
actually flowing.

> plus i
> can substitute in a lossy line and measure the line heating and
> measure no i^2r loss that would exist if there were currents flowing
> in the line, so there are none.

I certainly agree that there is no real current flowing, but the
fictititious If and Ir are indeed present (or pick a better word
if you like).

> try this case, which is something we do at work... take a 14ga piece

> wire should it? and yet it never does... so why doesn't it have your
> circulating currents

I really like this example. I thought of using something similar once
to convince Cecil, but never did. He is unreedemable. But your
example aptly demonstrates why If and Ir are not real, though still
useful because If-Ir is the actual current flowing.

Just as an aside, your comment above about requiring a voltage to
cause a current to flow is not quite correct. An ideal conductor has
zero resistance, so current can flow without voltage in an ideal
conductor. Strangely, this can even be achieved in the real world
with superconductors.

So I offer another example for your consideration. The experiment
is the same as above (100V, 50 ohm, ideal source and conductors)
but this time short the end of the transmission line. After waiting
for the line to settle, we find 0 volts everywhere and 2A flowing.
Recalling the coversion equations:
Vf(t)=(V(t)+R0*I(t))/2
Vr(t)=(V(t)-R0*I(t))/2
If(t)=Vf(t)/R0
Ir(t)=Vr(t)/R0

we obtain:
Vf(t)=(0+100)/2 = 50V
Vr(t)=(0-100)/2 = -50V
If(t)=1A
Ir(t)=-1A

Substituting to verify
V(t)=50+(-50)=0V
I(t)=1-(-1)=2A

Exactly as measured.

I will caution again, do not assign too much reality to these
forward and reflected waves; very useful for solving problems,
but trouble if carried too far.

...Keith

Quoting "Fields and Waves ...", by Ramo and Whinnery: "A perfect
conductor is usually understood to be a material in which there is no
electric field at any frequency. Maxwell's equations ensure that there
is then also no time-varying magnetic field in the perfect conductor."
How does one go from zero current to a non-zero current if the
magnetic field is prohibited from varying (changing) with time?

I'm afraid you are too late with that advice. Optical physicists have assigned reality to forward and reflected waves inside an interferometer and have tracked all of the energy including the energy in canceled wavefronts.

http://www.teachspin.com/instruments/moderni/experiments.shtml

Scroll down to, "Using Dielectric Beamsplitters to find the "missing energy" in destructive interference" It says: "... when interference is destructive at the standard output, it is constructive at the non-standard output."

In RF terms, when interference is destructive at a Z0-match, it is constructive in the direction of the load.

Inertia first Newton law applied to the free electron lttle balls
perhaps?
Now, if at first of experiment little balls was at rest, how do they
set in movement without a force? Tell us.
.....
Keith, OM, if you do not make the rope experiment, make this another
simple one => get from Radio Shack a long, long lossles TL, (with
vf=1, why not?), 6*10^8 meters long it is good, open or short ended
(it does not matter). Connect it to your 100 W rig, key for a one
second the TX full CW power, inmediately disconnect the TL and touch
the connector with your fingers. Just count: tree, two, one, ¡zero!.
If after "zero" you still with the connector in your fingers without
blink, then reflected waves really have not too much reality... have
some ointment for burns, may be the boys are right.>) (sorry, do not
be angry with me I am practicing translate some creole humor to
english :>D)

It would be really really REALLY effing great if you dorks would take
this to a suitable forum. This has nothing to do with antennas.

And it is an unproductive infinite length, in case you bunch have missed
that point. But I'm guessing that given how intelligent you all are,
you already figured that out, and are ignoring it. No one is changing
their position, and they never will.

And yes, I have the thread set to "ignore". Which everyone should.

I will NOT see your responses.

Dear Roy:
This is a brilliant piece of work, it clarify so much misconceptions
(or extension of certain concepts beyond its scope). However the
question of "why" persist floating somehow.
Without leaving conventional approachs I think in the article cited in
the "Where does it go?" thread there are some helpful and valuable
hints: http://www.ittc.ku.edu/~jstiles/622/handouts/Transmission_Lines_package.pdf

Page 25 => "The precise values of Vo+, Io+ Vo+ and Io- are therefore
determined by satisfying the boundary conditions applied at each end
ofthe transmission line.
Page 28 => Although Vo+- and Io+- are determined by boundary
conditions
(i.e., what’s connected to either end of the transmission line),
the ratio V+- / V+- is determined by the parameters of the
transmission line only (R, L, G, C).

What it is your opinion about?

Hello Miguel,

The part of the paper you quote is very standard transmission line analysis which can be found in any textbook on the subject -- although I find this treatment to be better written than most. Nothing I have ever posted contradicts, or intends to contradict, the very well known and established theory which has been found to be correct and useful for over a hundred years. What I find silly is the idea that there are waves of average power bouncing back and forth, needing to "go" somewhere, and the specious arguments put forth in desperate attempts to explain where these elusive waves "go" and how they supposedly behave. (But interestingly, people seem much less concerned about where that extra "forward power" comes from.) It's very much like a pseudo-scientific exposition on the nature of ghosts or arguments about the effects of various astrological signs.

As you've hopefully seen from my few recent postings, it's painfully simple to show that most of the conceptions about these power waves are ridiculous. But one can't change someone's religion by means of rational arguments, and it's a fool's errand to try. So my postings aren't directed to the power-wave zealots but rather to the few people who are still open to reason. I see you're one of them, and I'm glad you've

giving the topic some careful thought.

but that is NOT a "second' mechanism. it IS superposition, which is
what you agreed to earlier, maybe in a different thread. the
mechanism is superposition, the observation is that the waves
interfere either constructively or destructively.

> the energy in the canceled wavefronts back toward the load. This step

Good day Miguel,

In the example you provide, there would be real energy flowing and
it would be clearly shown by
P(t)=V(t)*I(t)
P(t) will be negative because the energy is flowing in the reverse
direction.

Computing Pf and Pr would reveal
Pf(t)=0
Pr(t)=-P(t)

So Pf(t)-Pr(t) => P(t) as it must.

I see no conflict with anything that I have written previously.

There are many examples where one can observe energy flow in a
reflected wave.

It just takes one counter-example to demonstrate that this is not
always
the case and that one should not assign *too* much reality to such
waves.

What this neans is that when someone asks "what happesn to reflected
energy?", the first question you have to answer is "Is this a
situation
where the computed reflected power represents something real?"
because
if it does not, the original question is moot.

...Keith

fictitious?? i can measure them, watch them flow from here to there,
and see physical effects of them, doesn't sound very fictitious to
me. weren't you the one who teaches tdr use? what are you seeing in
the steps of the tdr if not for reflected waves coming back to your
scope?

>
> That is why they are quite analogous to the two currents in the two

no, that is why they aren't analogous. lumped components can't
represent the traveling waves.

no it isn't. in the limit at R->0 0V/R still looks like 0 to me.

now you say they are fictitious, yet you have formulas for them and can measure them... until you come to your senses and admit that reflections are real there isn't much we can do for you so the rest of your post is based on an incorrect premise.

Actually, I'm following and enjoying the conversation. Since you set
your computer to ignore responses, then you should have no objection if
they continue. It makes more sense to ignore subjects which don't
interest you than to complain about them.

> its really the voltage and current reflection coefficient.

It's really an electromagnetic wave obeying all the laws of physics
for an electromagnetic wave INCLUDING ENERGY CONTENT. ExH is the power
density of the wave and the voltage coefficient squared is the power
reflection coefficient. All of the power/energy math used on a Z0-
match gives identical answers as using the voltages PLUS it answers
the original question asked by the first poster to this thread about
what happens to reflected energy. The answer is that reflected energy,
like any other energy, is conserved traveling at the speed of light in
the medium, until it is dissipated or radiated.

Try measuring the voltage and current content of a laser beam and you
will realize why optical physicists are decades ahead of RF engineers
in understanding where EM wave energy goes.

> > This [superposition] is the second mechanism (wave cancellation) that redistributes
>
> but that is NOT a "second' mechanism. it IS superposition, which is
> what you agreed to earlier, maybe in a different thread.

In my statement above "This" refers to "superposition" which is the
second mechanism after reflection, the first mechanism. ***I REPEAT!
(1) REFLECTION IS NOT THE SAME AS (2) SUPERPOSITION!!!*** You are now
just engaging in obfuscation of what I have said. I expect such shabby
behavior from others on this newsgroup, but not from you.

Wave cancellation is just a special case of superposition, i.e. wave
cancellation is superposition.

(2nd mechanism) Superposition ==> Interference ==> Wave Cancellation,
which is ***NOT*** the same as
(1st mechanism) Reflection. I cannot say it any plainer than that.

Exactly! The method that most RF engineers use does not tell how the
energy flows. Witness the posters who are implying that a reflected
wave contains no energy because they cannot figure out where that
energy goes or how it gets there. In his food-for-thought example,
w7el completely ignores the role of superposition/interference in
redistributing the energy, a phenomenon known and understood in the
field of optical physics for at least a century.

On the contrary, what you have said indeed does contradict 100 years
of optical physics. All you have to do to alleviate your ignorance is
to grok that superposition (wave-cancellation/interference) can and
does redistribute energy even when there are no reflections present.
The ONLY time that a forward wave and a reflected wave don't interfere
with each other is when they are 90 degrees different in phase.

Have you never stood in a hall of mirrors where the reflections seem
to go on out to infinity on both sides? You would have us believe that
those reflections are not bouncing back and forth, mirror to mirror,
and that those reflections that you can see with your own eyes have
zero energy??? Roy, you are just spouting guru-type metaphysics, and
should be ashamed of yourself for trying to spread your religion to
the unwashed masses.

Hi,

I'm not sure if this is the right group btw.
I have an archos mp3 recorder with a 20gb hardrive
in it. It has a stereo line in I use to record
talk shows from a grundig radio.

When I record one particular fm station, a static
pulse is heard thru the headphone monitor
output of the archos. This pulse gets recorded
and I want to get rid of it. It is not heard thru
the grundig's speaker however.
No matter where I position
the archos, using a long cable, and no matter
where I position the antenna, this loud
pulse comes through the headphone monitor.
Why does this not come
thru the actual radio, and not other stations,
but only on this one station?

Thanks,

itchy

It certainly depends upon your definition of "power" and that definition is different between pure physics and RF engineering. One of the accepted definitions of "power" in "The IEEE Dictionary" contradicts the definition of "power" given in my college physics book. "The IEEE Dictionary" says that flowing energy passing a fixed measurement point is power, by definition.

If there is anything at all that can be measured, it must necessarily contain energy. If the EM energy is moving, it is power, by IEEE definition. If you disagree, take it up with The IEEE.

So the actual question that needs to be answered is: Does the electromagnetic reflected wave contain energy traveling at the speed of light in the medium? The answer is yes, being photonic in nature, an EM wave must necessarily contain an ExH power density and, consisting of photons, must necessarily be traveling at the speed of light in the medium. The EM wave will continue to travel in the direction of energy flow at the speed of light in the medium until it encounters an impedance discontinuity which causes a reflection and/or interference.

There is really no difference in a forward wave and a reflected wave except for the direction of travel. They both contain an associated ExH power density. One can set up identical signal generators at each end of a transmission line to emulate forward and reflected waves. Which generator yields forward waves and which generator yields reflected waves? It doesn't really matter because direction is only a convention.

because, at least when i do circuit design, i NEVER calculate energy,
and only at the end calculate power if i really need to. voltage and
current or E and H are the simpler things to handle and totally
sufficient for all circuit analysis, either lumped or distributed.

try listening to the line out from the grundig directly, you may be
able to hear it in a set of headphones, or you may need some amplified
speakers. see if there is noise there that isn't in the speaker...
then turn on the mp3 to record near to the grundig... there is an
outside posibility that the mp3 recorder is transmitting a noise that
the grundig picks up on that one station's frequency, you may only
hear it when the mp3 recorder is connected to the grundig because it
is conducted on the cable.

When I said reflection is the first mechanism and superposition is the second mechanism, you said: "... but that [referring to superposition] is NOT a "second' mechanism." The implication seemed clear to me.

Good grief, everyone is free to review what I said and what you said in disagreement. I said reflection is the first mechanism and superposition is the second mechanism. You said superposition is NOT a second mechanism, clearly implying that superposition is the same as the first mechanism which was already defined by me as reflection. Your implication was clearly that reflection and superposition are the same mechanism.

Do you agree that wave reflection can cause a redistribution of wave energy?

Do you agree that superposition can cause a redistribution of wave energy?

Do you agree that wave reflection and wave superposition are two different mechanisms?

If so, you agree with everything I have previously said and are now just blowing smoke. If you misspoke, just admit it. If you misunderstood what I said, just admit it. If you have changed your mind, just admit it. If you still disagree with any of those three statements, please continue the argument that you started in response to my assertion that there exists two mechanisms that can redistribute energy in a transmission line, (1) reflection and (2) superposition.

Hello friends. good day for you.

I am glad that I have not bothered with my joke, Keith! :>) I was to
do some comments to your and Roy posts, but I prefer to ask questions
rather than giving personal opinions :>)
....
Please Cecil, friend, do not mention photons and optics (do not bother

me, don't worry), I believe you better play your game without such things. I know is like fighting with one arm tied, but I think you can, make an effort :>)

Please Owen explain to me what is "negative power".

In the other thread you said => "The notion that reflected power is simply and always absorbed in the real source resistance is quite wrong. Sure you can build special cases where that might happen, but there is more to it. Thinking of the reflected wave as 'reflected power' leads to some of the misconception.
Then I asked; "remember me what reflected power definition are you using here and expand the sentence idea".
I did not ask for the quoting, I ask (again) for your concept of Reflected Power. I do not sure if you accept (or not) the very notion of reflected power as legitimate. The sentence it is not clear enough to me.

Please, tell us if you accept the idea of two very directive electromagnetic waves from different sources flowing in opposite directions as carring independent energy (with different frequencies at first) and information, and the posibbility that energy be dissipated and/or transmitted by de opposite system and the information being recovered in both ends.
If your answer is yes, then tell us if you conceive such similar system using a same wave guide to simultaneously vinculate both system.

73 - Miguel - LU6ETJ

PS: Roy, friend, take it ease (is OK, or polite say "take it easy?), references to the article were only to complement (bring close?) some useful notions related, mentioning a possible common reference (my english books are few, old and possibly useless as reference nowadays)

no. wave reflection causes current and voltage waves to change
direction, magnitude, and phase.

>
> Do you agree that superposition can cause a redistribution of wave
> energy?

your observed 'redistribution of wave energy' is a results of
superposition of current and voltage waves and then another
calculation to convert the sum to power and another calculation to
integrate the energy.

>

The question asked by the original poster is, exactly what happens to the reflected energy? Optical physicists know that a reversal of energy flow direction accompanies the change in direction of the E-field and the B-field which changes the direction of the ExB Poynting vector, i.e. changes the "direction and momentum" of the EM wave according to Eugene Hecht. How can you not know that a voltage/current wave requires energy? How can the voltage and current change direction without the energy changing direction? Does supernatural intervention separate the voltage and current from the ExH energy?

Maybe you should reference, "Fields and Waves ...", by Ramo and Whinnery where they describe the forward and reflected power-density Poynting vectors.

Is that a yes or no answer? The same thing happens with light waves in free space where voltage and current are completely irrelevant.

> > Do you agree that wave reflection and wave superposition are two
> > different mechanisms?
>
> of course, i've never said otherwise.

You sure implied otherwise. Why did you argue with me when I said they are two different mechanisms in action to redistribute energy, (1) reflection and (2) superposition? You said superposition is not the second mechanism.

What do I do about people who assert that RF waves possess the ability
to violate the known laws of EM wave physics? It doesn't matter what
the frequency of an EM wave is, it must obey the laws of physics, two
of which are:

1. It cannot exist without a Poynting vector ExH power density.

2. It must necessarily move at the speed of light in the medium.

energy?-"
"-No. wave reflection causes current and voltage waves to change direction, magnitude, and phase.-"

You see? Babel curse...! One ask about energy other answer with current, voltage, etc. (same thing divided in pieces).

Do you agree cars have engines?, ¡Of course not! ¡cars have crankshaft, cylinder, piston, rods...!
Thus you are never going to reach an agreement :D :D

> what does yours read?

That would most likely be because your wattmeter is AC coupled.
Working
with DC, you need a DC-coupled meter, in which case it would read as
I predicted.

A highly instructive exercise is to examine the schematic for your
directional wattmeter and work out how it implements the expressions
Vf(t)=(V(t)+R0*I(t))/2
Vr(t)=(V(t)-R0*I(t))/2

Pf=avg(Vf(t)*Vf(t)/R0)
Pr=avg(Vr(t)*Vr(t)/R0)
or some equivalent variant using If and Ir.

You will find a voltage sampler, a current sampler, some scaling,
and an addition (or subtraction). If your meter is analog, the
squaring function is usually implemented in the non-linear meter
scale. And the averaging function might be peak-reading or rely
on meter inertia.

When computing the intermediate results using superposition, you
have the full battery voltage in to 0 ohms. First the battery on
the left, then the one on the right, and then you add the two
currents to get the total current. 0 is always the total, but
the intermediate results can go to infinity if you connect
the two batteries directly in parallel.

Then what are the equations for computing forward and reflected waves and 'power'? That is where I started. Is that the premise you consider to be incorrect?

Do follow through the arithmetic in the previously provided examples and see if you can find any faults. Point me to any errors and I will gladly reconsider my position.

If not, perhaps it is time for you to start questioning your assumptions.

mine is dc coupled... still nothing. please provide the schematic or
model number for the one you use to get such a reading.

there is no battery on the right, unless you have changed the case
again. i thought we were doing the open circuit coax with the dc
source on one end.

but even if you have the case above and connect another 100v battery
on the open end of the line there will be no current flowing back as
there is no voltage difference to drive it.

yep, your 'waves' don't include the proper term to make them
propagating waves that satisfy maxwell's equations... so they can't be
real... so your initial premise is incorrect.

my assumptions are perfectly valid... it is yours that are flawed from
the very beginning.

One does, however, usually require that the more sophisticated model
continue to provide the correct answer for the simpler problems that
could be solved in another way.

And it does here as well, though the answers make some uncomfortable.

> > Still, I observe that you have discovered no errors in the exposition.
>
> I have not wasted my time time trying to discover any errors. In a
> nutshell, what new knowledge have you presented?

Well, at least you continue to read the posts, so perhaps there is
some slim hope, but I am not holding my breath.

As for me, I have learned a lot from your postings since I first
encountered them circa 1994. Back then, I was not so knowledgeable
about transmission lines and I was trying to decide who was right.
You posted well thought out, convincing arguments and I found myself
switching from side to side. Reflected waves heat finals, no they
don't, yes they do, ... but eventually I learned. Then I continued
to read your posts, visited your web site and studied your arguments.
The challenge was to discover where you had gone wrong. Occasionally
I would think up a suitable counter example and offer it to you, but,
even then, you refused to look at examples that might threaten your
beliefs. So I no longer post with any expectation that you might be
persuaded.

Mostly now I post to ensure that a view other than yours is voiced
to help prevent those who are not yet sure from being sucked in to
your vortex.

Anyhow, I suggest you read my examples and find the flaws, for that
is the surest way to convince me that I am wrong. And don't just
post other examples that support your position, for it only takes
one counter-example to disprove a hypothesis, no matter how many
examples are in agreement. And don't reject simple DC examples

because
they lead to uncomfortable answers for it is by examining the
examples
that do not support your hypotheses that you will learn, not by
sticking
just with the ones that do.

Oh my. Could you kindly provide the schematic or a reference? Before
posting I spent an hour searching my library and the web for the
circuit
for a dc-coupled directional wattmeter and was unsuccessful.

Nothing prevents one from being constructed. That one is not readily
available should not prevent you from using the equations that they
implement and then predicting the DC behaviour of the line.

No. I was referring to the simple DC circuit with two batteries and
a resistor. I was pretty sure that was your referent when you used
"R->0".

I understand that you have not found any flaws in my exposition,
except that you are still uncomfortable with the results. It is
possible to overcome this.

And I re-iterate the value of studying your directional wattmeter's
schematic, especially if it is DC-coupled.

You have fallen in to the same trap that you did with circulators.
When you introduce a circulator in to the transmission line, you
change the experiment and you get certain results. The circulator
provides some numerology that appears to support the hypothesis
of 'reflected energy' being real. The same with looking for
"missing energy" (note they even quote it) with a beamsplitter.
The beamsplitter reveals what is happening at the beamsplitter,
not what is happening at points between the two beamsplitters.

Just like a circulator.

he is even more hopeless than most, first he determines there are forward and reflected waves when a dc source has charged the line, then he rejects circulators and beamsplitters that obviously work because of the waves. so dc waves exist, but rf and optical waves don't. thats a unique viewpoint.

It appears that you are a masochist [to yourself] or a sadist [to the kid you had use a sledgehammer !!! There is a much, much easier device, to place ground rods in place. It's called a 'Water Drill'. You use typically 3/4" galvanized steel pipe of the appropriate length {couple lengths together, as needed}, add a 1' > 2' section at a right angle to the main vertical length, for rotational/insertion/extraction leverage. On the end of the short piece, add a female hose [with a water shut-off] to pipe adapter. On the vertical pipe, add a older style adjustable brass spray nozzle. You usually want a forceful stream. Simply place the nozzle end where you desire to begin a hole for the ground rod. Turn on the water (wear a raincoat/wetsuit, if you like), and apply slight downward pressure. You may need to alternately extract and reinsert, to allow dirt, from the hole being drilled, to escape.

This procedure, very possibly, may not work in VE6 land; in the wintertime. Where I live, I can drill a hole in usually less than 5 minutes, and drop in the ground rod shortly thereafter.

Hi

I'm after some FB-31-1020 ferrite rings to go on my Hexbeam.

Any one know where I can get some from here in the UK or is there an equivalent I can get?

Thanks

I have plans for a very good 6 element beam which is 15.53 feet from reflector to D4. I could scale it to the element taper you have if needed.

It will not be a direct connect however, as those are almost never optimal designs for gain, F/B or pattern. They are optimized to be 50 ohms with the rest subservient to that. Most of the designs I have would be around 22 ohms so this one is probably in that area. A gamma match is easy to make.

There are at least 3 reasons to use some kind of a matching network.
1. impedance transformation - usually the feedpoint impedance of a
simple dipole in a yagi is not near 50 ohms so the matching system
gives you an easy way to adjust that.
2. it is often easier to build an aluminum element without a center
insulator and feed it with something like a gamma or T match.
3. to keep current off the feedline shield you need to go from the
unbalanced coax to a balanced dipole feedpoint. gamma matches and
others do that transformation for you.

2632. Ringo Ranger 2Mtr on 6Mtr

I have an old 2-meter Ringo Ranger on top of the tower
that has not been used for some time. I wonder how it
will do for six meters?

None of my SWR boxes cover VHF so may have to just
give it try and see what happens.

Wish me luck

It was a good idea that DID NOT work. The SWR as shown
on rig's s-meter was terrible and I could tell it was not hearing
as well as the fan dipole.

I am in agreement with all your points. [Not that I am any kind of
authority!]

Many years back I purchased and installed a Cushcraft A3S tri band
beam with the 40 Meter option. The decision was based on past
experience with Cushcraft products.

When I assembled it I was disappointed to find it did not have a gamma
match! Instead it got by with a direct connection to the driven
element with the 50 ohm line. Then it used a jury rig device called a
"choke balun" to keep the RF where it ought to be... It reminded me of
the Gotham Vertical (Google it!) that so many of us fell for way back
when. I assembled and installed it according to the instructions any

way. Much to my surprise, it worked great! I have been very happy with it.

That led to my taking the ARRL Antenna course and buying the EZNEC program.

Some things I model I can make work and some I cannot.
Some things work I cannot model.
I have concluded that direct connection and gamma matches both work well.

My cumulative experience is that it is difficult to beat the commercial products at their game.

OTH, the study and construction of antennas has become one of my favorite recreational pastimes!

2637. Tapering open wire feedlines?

Newsgroup: rec.radio.amateur.antenna
Date: 2010-06-20 15:04:23 UTC
From: Pete Bertini <radioconnection@cox.net>
Message-ID: <76qTn.8899$1Q5.3711@newsfe08.iad>
Source record: 8837

Just curious if this has ever been done? I'm thinking about
putting up a 90 foot dipole feed with homemade open wire
line. I'd like to bring it into the shack using paralled runs
of LMR-400 cable, since the final 25 feet is via 3" electrical
conduit that also has rotor and other cables.

I believe the parallel cables with give me a 100 ohm impedance.
The open wire will be using #10 with homemade spreaders,
I'm going to try for 600 ohms at the feedpoint. I was wondering
if tapering the spacing on the feedline would give me a smoother
impedance where the open wire, arrestor, and twin coax arrange-
meet?

define "rf ground".

Something that provides a counterpoise for an unbalanced feedline
situation that doesn't result in RF energy being wasted to heat
earthworms, soil, etc. and radiates RF energy efficiently.

My "ARRL Antenna Book", 20th edition, has a section on "Tapered
Lines". They say it should be at lease one wavelength on the lowest
frequency of operation. They give an "air insulated" formula for such
a design.

Cushcraft prided themselves on building antennas with a DC resistance of
0 ohms.

In plain English they were static disipators. At their design frequency
they had an impedance of 50 ohms.

When I lived in Philly, we had a sever lightening problem. Whenever there
were lightening storms there were nearby strikes with all sorts of expensive
EMP problems.

When I put up a cushcraft 2m beam (the 11 element vertical polarization on
the same beam as an 11 element horizontal one) with proper gounding they
all "went away". I wonder if our neighbors suddenly noticed next spring that
the lightening had come back :-)

Geoff.

the ground radiates? that's interesting.

so the raised radials on my 80m 4-square would be considered an rf
ground?

Yes, it has been done. Jasik's "Antenna Engineering Handbook" discusses tapered lines in section 31.4. You can also find a discussion of tapered-line matching in Laport's "Radio Antenna Engineering" in section 4.4.8 (this book is available as a free PDF download).

In your application, though, I'm not sure why you would want to bother. Traditionally, tapered lines are used as part of a matching network, making a transition between two known resistive impedances (e.g. transmitter and antenna).

That's not really the situation you seem to be setting up. You are (I presume) setting up a single doublet, to be used at multiple frequencies, with wildly varying impedances at the antenna feedpoint. You're then coming back to the shack with a high-impedance feedline (which has relatively low losses even at the high SWRs it'll be operating at), and then matching the impedance in the shack with a good transmatch-and-balun.

In a setup like this, the characteristic impedance of the open-wire line isn't particularly critical.. because it'll almost never be a close match to what the antenna is presenting at any given frequency. 600 ohms is a common feedline impedance... but no matter what impedance you choose here, it's unlikely to be a close match to the antenna under actual operating conditions. As a result, the impedance you actually "see" looking up into the lower end of the open-wire line won't be 600 ohms (if untapered) or 100 ohms (if tapered down close together). Rather, it'll be the feedpoint impedance of the antenna at the frequency in question, transformed by the feedline (tapered or not). You could calculate it, knowing the antenna's feedpoint impedance (e.g. from modeling it in NEC2) and the length and Z of the feedline... but it isn't likely to be close to a convenient pure

resistance except by lucky chance!

Hence, there's no real need to "match" the lower Z of the parallel-coax segment (100 ohms nominal) to Z of the open-wire line, since the latter value isn't actually what you'd have to match to!

Now, if you're planning to operate at a specific single frequency, you could perhaps utilize a tapered open-wire line as part of a tuned matching setup... in effect, designing the taper for that one antenna and frequency, in order to present a more convenient impedance to your transmitter's matching network (e.g. your external wide-range transmatch). However, optimizing the system in this way, for one specific frequency, might well make the antenna-and-feedline a *harder* load for you to match in the shack at other frequencies.

Yes, but will the configuration have the benefits you think? See
http://www.vk1od.net/transmissionline/stcm/index.htm for more info.

> The open wire will be using #10 with homemade spreaders,
> I'm going to try for 600 ohms at the feedpoint. I was wondering

What is 600 ohms, the feed line or the antenna.

If the feed line operates at high VSWR, it doesn't matter a lot what Zo
is. Further, that using tapered lines as a broadband impedance match
requires that the taper section is quite long wrt wavelength.

> if tapering the spacing on the feedline would give me a smoother
> impedance where the open wire, arrestor, and twin coax arrange-
> meet?

I cannot reconcile the 90' dipole and 600 ohms from the little
information you have given.

Your post is very short on information, so it is entirely a guessing
game.

Owen

Based on my personal experience trying to replace the inside shack portion of 600 ohm open feed line with two parallel pieces of RG-213 about 8 ft. long. The coax sections will effectively kill the use of your dipole on any of the higher frequencies. As I remember, the antenna was usable up through 10 meters , but after putting in the coax, I couldn't tune the system above 20 meters.

My antenna is a full sized 160 meter horizontal loop in the form of a trapazoid, almost a square, up at 35 ft. Fed in one corner with 600 ohm open wire,125 ft. long. The feedline comes into the house (mfg home with aluminum siding) using two Birnbach feed through insulators. Then to a DPDT antenna switch to ground the system during thunder storms, and finally about 6 ft of 600 ohm feed line to the balun in the Dentron MT-3000 tuner.

I think the problem with using the double coax is the very large capacitance it adds to the feed line, effectively becoming a low pass filter. Could be mistaken about the cause, but not the symptoms. I have actually used the system to make some local 6 meter contacts.

Try it anyway, but be prepared to go all the way to the shack with your 600 ohm feed line.

Well Dick, you only asked for positive responses, and you go none... so no surprises.

The matching arrangement on the Ringo is a quite narrow band one, so you should expect that it will not work well on 6m.

It is not uncommon to hear of people on HF using a 11m end fed half wave with narrowband matching (ie similar to the Ringo) on the lower bands (eg 7MHz) with the 'assistance' of an ATU. I quote 'assistance' because the ATU does assist in obtaining a good VSWR for the transceiver, but probably converts most of the transmitter to heat. A good example of the failure of an entirely VSWR focused approach.

An ATU can hide a multitude of sins.

Owen

The coax is, and always is a transmission line, and at the length you described cannot be approximated well as a shunt capacitance.

What you have is a cascade of two line sections, one of say 600 ohms, then one of 100 ohms, and each is probably operating with standing waves, so there is impedance transformation.

To illustrate, lets say your feedpoint at 3.6MHz with a certain loop antenna was 100+j0, and you had say 30m (100') of 600 ohm open wire, the impedance looking into that would be around 240-j675. If you feed that with say 6m (20') of LMR400 twin, then input Z would be around 60+j260 and loss would be about 40%.

The synthesised shielded pair is relatively lossy, and low Zo. Most people use this configuration thinking that the shielding prevents external fields from common mode current, but they are quite wrong. See http://www.vk1od.net/transmissionline/stcm/index.htm .

Though the traditional approach has been to use a 4:1 voltage balun at the rig to feed these things, there is good argument to use a 1:1 Guanella balun (current balun), and it can be located outside the shack and inboard shield effectively grounded to deal with common mode current. You still need to minimise the length of coax operated at high VSWR, and it would not be necessarily absurd to think about low loss coax.

Approximating coax as a shunt capacitance might be reasonably accurate for some applications at audio frequencies, but it is probably not for most RF applications.

Owen, my thinking was to make a transmission line with a characteristic
impedance that gradually changed from 600 ohms down to as close to

200 ohms as practical, just to avoid the impedance bump at the junction of the open wire and shielded balance line. I've found a few references that state the taper should follow a log response; and also if the line needs to be a wavelength or longer pretty much dashes that idea. It would be a lot easier to construct a line with charateristic impedance of 400 to 600 ohms, and deal with narrow spacing issue for only a relatively short portion of the entire span.

I didn't expect the shielded cable to be immune to common reradiation problems, but that issue could be dealt with separately if it was a problem. Pete

the ground radiates? that's interesting.

so the raised radials on my 80m 4-square would be considered an rf
ground?

I would consider them to be an effective RF ground at their 1/4
wave resonant points, just as would a tuned artificial RF ground
used for stations at elevated locations.

Pete

Okay, then it might make sense to do this: Plan II

instead of using the balun is in the tuner, there is no reason
why I couldn't mount another 4:1 balun outdoors, and use a short run
of low loss coax back through the conduit into the operating room.

That would be about 15 feet of LMR-400 cable. I could go to 1/2 heliax
but would there be any benefit??

So, I would have balanced open-wire feedline from the dipole to
the 4:1 balun followed by a 1:1 common-mode RF choke with
the requiste RF ground for decoupling,
followed by the short run of low loss coax going back to a
unbalanced ant. port on the tuner. I'd still have coax in the mix,
but the 4:1 balun should hopefully tame the high impedance
excursions across the antenna operating range to
reduce the coax's losses at those points?

Otherwise it is going to be hard to get balanced line into the shack,
unless I pull it through the PVC conduit with the other coax cables.

Pete

See my article entitled "Is a 4:1 balun a good choice for use with an ATU
on HF?" at http://vk1od.net/blog/?p=987 .

It is difficult to answer the question about the LDF without knowing the
impedances involved. I used TLLC (http://www.vk1od.net/calc/tl/tllc.php)
to work the examples I gave, you could do the same if you know the
feedpoint impedance etc.

If you want to solve the cases for an arbitrary two wire line, try
http://www.vk1od.net/calc/tl/twllc.htm .

I should have mentioned that 4:1 baluns integrated into ATUs are most often voltage baluns.

When operated near a voltage maximum with high standing waves, they can be very lossy. Sometimes it is claimed that they 'tame' difficult antennas better than current baluns, which is often due to their internal loss. The problem as such is not the balun, it is the extreme load presented by a very poor antenna, and the lossy balun is a poor (grossly inefficient) circumvention.

So, when a 4:1 voltage balun allows a match where a 1:1 current balun doesn't, the problem is probably the antenna, not the balun.

You might consider the following experiment:

- a sinusoidal generator that will produce 50W in to 50 ohms
- attach one half wavelength of transmission line
- leave the far end of the transmission line open

After the line settles, a directional "wattmeter" anywhere on
the line will indicate 50W forward and 50W reflected.
The generator will not be putting any energy in to the line
since the line input appears as an open circuit at the
generator output.

Insert a circulator (with the reflected port terminated in
50 ohms) between the generator and the line. The circulator
termination will be dissipating 50W and the generator will
now be delivering 50W in to the circulator.

1. Please explain how inserting the circulator did not change
the circuit conditions. The generator went from delivering
0W to delivering 50W.

2. Where do you think the 50W being dissipated in the circulator
termination resistor is coming from? The line? Or the
generator (which is now outputting 50W)?

Just for fun, you may be interested in a DC coupled circulator
that works all the way down to 0 Hz:
http://www.techlib.com/files/RFDesign3.pdf

Answer question 2 for this circulator design.

2662. Idea: three bar antennas for clear portable AM radio listening

Newsgroup: rec.radio.amateur.antenna
Date: 2010-06-21 02:12:22 UTC
From: jidanni@jidanni.org
Message-ID: <87y6e9uo9lBLA.fsf@jidanni.org>
Source record: 8762

Gentlemen, I have an idea for a "portable AM radio" antenna to allow the user to hear the station clearly while walking, no matter what direction the radio is held.

Just have three bar antennas, aligned along the X, Y, and Z axes, like http://en.wikipedia.org/wiki/Jacks , or independently placed inside the case. A microchip would constantly pick the best signal from amongst them. Maybe even just two axes would do.

Great for farmers who are walking around all day, and just can't give up their favorite AM station for FM.

It has been done. It's a form of diversity reception. It would require a
radio with two separate receivers in it. I think the liklihood of a
manufacturer deciding to build a radio optimized for your two applications
is kinda slim.

Why not try two small radios and join their outputs? Mount them
corner-to-corner (90-degrees opposed) so that when one is
in the null, the other one is at the peak. Couple the hot sides
of each of the output jacks together through a pair of small resistors,
say 39 ohms. You probably need to know how to solder and
know where Radio Shack is for a few small parts.

Next time I'm at the swap meet, I'll see if I can find a matched set of
mini-cheapo portable radios and maybe try it myself.

> Reflected waves heat finals, no they
> don't, yes they do, ... but eventually I learned.

Hopefully, you learned that rail arguments are rarely valid and the truth usually lies somewhere in between. Sometimes reflected waves heat finals and sometimes they don't. It all depends on what kind and how much interference exists between the forward wave and reflected wave at the source impedance and (apparently) how much of that impedance is dissipative or non-dissipative. Roy's food-for-thought article doesn't take interference into account at all and therefore arrives at magic conclusions divorced from reality.

> Anyhow, I suggest you read my examples and find the flaws, for that
> is the surest way to convince me that I am wrong.

I have pointed out many of the flaws in your examples. The way you parse the energy violates the laws of physics. Maxwell's equations only work on a function that contains classic EM traveling waves. Standing waves and DC steady-state examples don't meet the necessary boundary conditions. In fact, it can be proved that EM waves do not existent during DC steady-state. The fact that an instrument designed to detect EM waves malfunctions during DC steady-state is not unexpected. Even an SWR meter calibrated for a different Z0 than the one being used will indicate false results.

You really need to learn to recognize when your experiment and your math model are contradictory, when your concepts violate the laws of physics, and when you have chosen the wrong measuring equipment. You remind me of myself when I was 14 years old and tried to measure the screen voltage on a vacuum tube using a Simpson multimeter. It wasn't anywhere near the voltage specified in the manual so I wasted my money by buying a new tube the next time my family made a trip to Houston.

You would report those same measurement results as proof of a strange, magical happening.

The generator went from experiencing total destructive interference to
experiencing zero interference. Of course, the entire purpose of
inserting the circulator is to cause the generator to see 50 ohms as a
load impedance.

> 2. Where do you think the 50W being dissipated in the circulator

TV ghosting experiments will verify that the signal being dissipated
in the circulator load resistor has made a round trip from the
generator to the end of the N(1/2WL) stub and back to the circulator.
Please don't insult our intelligence by arguing that is not a steady-
state condition.

It is my experience that the null of a ferrite bar antenna is very few
degrees,
making it a little dificult to get a good null.
I have not had a problem with AM.
FM on my mp3 player which uses the headphone cord as the antenna and
is a problem with respect to the direction and terrain around me.

Yes..

Tapered transmission lines have been around for decades, and work just
like you'd expect.

For the ultimate in performance, you actually want to use an exponential
taper (spacing increases by the same percentage per unit distance), but
a linear taper (spacing increases by the same distance per unit
distance) works pretty much the same, especially if the taper is "long"
(>10x) relative to the spacing. that is, going from 1" to 3" spacing
over a foot or two..

As an academic exercise, for example using a tapered
line to match an OCD with a known FP impedance of 200 ohms
down to a 1:1 balun at the 50 ohm coax line transition point.
What is the recommended minimum length of cable needed to
perform a four to one characteristic impedance change in the
open wire for relating to the wavelength?

What's the VSWR and frequency spec?

50 ohm balanced pair might be hard to come by.. the usual 276*log10(D/d) equation is only valid when D>>d. (D = spacing, d = diameter) and just ballparking 50 ohms means that the spacing between the wires is about 10% more than the diameter (D/d <1.1). 200 ohms is more like D/d = 3

Pete,

You really don't disclose very much, certainly not in a clear way. But,
some of your hints (eg OCD with open wire feed) leave me asking why? I am
not going to waste time writing a lot of words based on a hint though.

Owen

It's not practical to make a 50 ohm open wire line. The wires would have to be extremely close together.

But as to "recommended" minimum length, it depends on who does the recommending and what your criteria are. The length of line necessary to transition from one impedance to another depends on at least three things: the amount of transformation required, the type of taper (e.g., linear, exponential, Klopfenstein), and how close the impedance match has to be (usually specified as input reflection coefficient). There's a brief treatment in Johnson, _Antenna Engineering Handbook_.

In Brown, Sharpe, Hughes, and Post, _Lines, Waves, and Antennas_, it's stated that the tapered section must be at least a quarter wavelength long, and that if less than that, "it will fail in its matching function".

In Skilling, _Electric Transmission Lines_, ". . . a 2 to 1 change of characteristic impedance many be accomplished by using a tapered section that is 1 wavelength long. A good impedance match results at this frequency and at all higher frequencies. Results are fairly good if the tapered section is as little as 1/2 wavelength long, particularly if the impedance ratio required is less than 2 to 1. It is not worth while to use a tapered section much shorter than 1/2 wavelength, for a taper that is 1/4 wavelength or shorter will give nearly as much reflection as will the abrupt change of impedance at a mismatch. Those frequencies for which the length of the taper is a multiple of a half-wavelength are transmitted with the least reflection. This may be a guide in choosing the length of the taper." The author goes on to state that linear and exponential tapers give practically the same results, and summarizes with a recommendation that a tapered section be between 1/2 and 1 wavelength long at the lowest frequency of use.

Actually, a "GOOD" RF Ground will exhibit a very LOW Impedance across a broad Frequency Spectrum, and NOT just at any single Frequency.... When designing an RF Grounding System for a particular Site/Antenna System, it is almost as important to know the Frequencies, and Bandwidths, to be transmitted on, as it is to know the practical design of the Antenna itself. Earth Conductivity has a much smaller effect than most folks think.

Oh dear. What does this say about "Artificial RF Grounds?"
For that matter, is a tuned "artificial RF ground" a real "ground" or part
of the antenna's radiation system?

its part of the 'system' but radiating or not can be debated.

There are a couple problems when talking about RF Grounds.

You can not equalize the rf voltage over anything that is an appreciable fraction of a wavelength using any type or combination of rods, radials, screens, or rings... it just ain't possible. any ground system other than the fictional 'perfect' ground will have a pattern of voltage peaks and nulls much like standing waves in 2 or 3 dimensions. therefor you can not call any particular point on the ground system 'ground' for purposes of voltage measurements... nor can you trust any particular point to be equal to any other point, so you can get rf burns while standing on a 'ground' screen and touching a coax shield or neutral or 'ground' power cable.

The whole purpose of the 'artificial' ground is to force one of the voltage nulls to be where it will do the most good... if that means you have problems with rf getting into your computer keyboard, or get burnt by the mic when you swallow it, you can 'tune' the ground to cancel out that effect locally... of course that means that there will be changes in other places that may cause other problems, but at least you won't get burned.

Now, on to the 'rf ground' as it applies to something you build under a vertical radiator.... sorry, this will have to wait... just sleep on currents going up the vertical having to be equal and opposite all the currents flowing back into the shield side of the coax... no matter where they come from, and imagine all the chances for currents to be where you don't want them.

Along with the other use for circulators: To present an impedance
match to the reflected wave so that it will not be re-reflected.

It is not clear why you think this verifies something.

Enhancing the details slightly of the generator in the original
example: The generator is constructed using the Thevenin model
of a source followed by a 50ohm resistor.

With the circulator, there is no re-reflection at the driven
end of the line, 50W is dissipated in the circulator
resistor and 50W is dissipated in the source resistor.

Without the circulator, there is no re-reflection and nothing is
dissipated in the source resistor (and there is no circulator
resistor).

The dissipation seems to correlate much more strongly with the
circuit design than it does with the magnitude of the "reflected
power".

> Please don't insult our intelligence by arguing that is not a steady-
> state condition.

Well you are right, it is not steady-state when there is modulation,
but modulation does not affect the examples I have provided.

...Keith

PS: For further understanding, substitute a Norton style generator,
then do it again for both kinds of generators but with the end
of the line shorted yielding more examples where the "reflected
power" does not correlate with the dissipation.

The simple radio do not work without the ground:
http://scitoys.com/scitoys/scitoys/radio/am_transmitter.html

"Without any connection to an antenna or a good ground connection, the
transmitter will only transmit to a receiver a few inches away. To get
better range, clip the ground wire to a good ground, such as a cold water
pipe, and the antenna to a long wire, like the one we used for the crystal
radio."

Is it possible to measure the netto current in the track ground-antenna?

The field emisssion probably works in an antenna: "Field emission can happen
from solid and liquid surfaces, or individual atoms into vacuum or open
air,"

> course.

That is the classic answer from the “reflected power” model, but
consider the following...

We construct two experiments similar to the above.
The first one:
- a sinusoidal generator that will produce 50W in to 50 ohms
- attach one half wavelength of transmission line
- leave the far end of the transmission line open
- the generator is constructed in the Thevenin style with a
voltage source and 50 ohm resistor

The second experiment:
- same as above except there is a circulator between the
generator and the line and the circulator is terminated

with 50 ohms

Examine experiment 1. After the line settles, a directional wattmeter indicates 50W “forward power” and 50W “reflected power”. The current in the voltage source and source resistor is 0 so no energy is dissipated in the source resistor and the voltage source is delivering no energy to the system. The “reflected power” is not being dissipated in the source resistor or voltage source so where is it going. Cecil will offer some explanation where the “reflected energy” is “redistributed” in the other direction as the “forward energy”, which “must” be happening since it is not dissipated in the source and it can not be reflected because there is no impedance discontinuity.

Examine experiment 2. After the line settles, a directional wattmeter indicates 50W “forward power” and 50W “reflected power”. But with a circulator, the voltage source is delivering 100W, the source resistor is dissipating 50W and the circulator resistor is also dissipating 50W. You offer that the 50W being dissipated in the circulator is the 50W of “reflected power” coming from the line. Presumably then, the 50W of “forward power” is coming from the generator. This agrees numerically since the voltage source is providing 100W and the source resistor is dissipating 50W.

In both experiments, conditions on the line are identical. There is 50W of “forward and reflected power” indicated. There is no energy flowing past the end of the line since it is open circuited.
Because the line is one-half wavelength long, the line presents an open circuit to the generator (exp 1) or circulator (exp 2).

In both experiments, the line is presented with a 50 ohm source impedance, either from the generator or from the circulator.

What puzzles me then, is how the “reflected power” knows that in experiment 1, it should stay out of the generator so that it is not dissipated in the source resistor but in experiment 2, it should enter the circulator so that it can be dissipated in the circulator load resistor.

Can you explain how the “reflected power” “knows”?

...Keith

Given a 50 ohm source resistor resulting in zero re-reflections, *the dissipation correlates perfectly with the level and type of interference*. I am amazed at the level of ignorance concerning interference and the conservation of energy principle. I studied interference in detail in my 1950's college physics courses including what happens to the energy during interference events. Although Dr. Best didn't realize it, in his QEX Nov/Dec 2001 article on transmission lines, he presented the equations governing energy redistribution associated with interference. What didn't help was his equation of the form:

Ptot = 75w + 8.33w = 133.33w

which is obviously false. What he left out was the constructive interference term of:

2*SQRT(75w*8.33w) = 50w

Given two coherent waves, each associated with a Poynting Vector, when those two waves are superposed, interference will result. I'm sure everyone has seen interference rings and pictures of interference rings where the energy in the interference rings has obviously been redistributed away from a homogeneous power density. The same thing happens in a transmission line and/or at a source, just at longer wavelengths where we cannot "see" them with our eyes.

Constructive interference requires "extra" energy. Superpose two 50 watt coherent waves in phase and the result is a 200 watt wave. Destructive interference has energy left over. Superpose two 50 watt coherent waves 180 degrees out of phase and the result is a zero watt wave. At a source, the source is capable of supplying extra power or throttling back on its power output depending on the level and kind of interference. If one simply takes the time to understand interference, one knows where the energy components go even when there is zero re-reflection.

Given a single traveling wave in a lossless transmission line with a purely resistive characteristic impedance of Z0, the power (joules/second) measured at a point on the line is P=V^2/Z0=I^2*Z0=V*I. This is classic transmission line math no matter which direction the wave is traveling. Superposing two coherent traveling waves cannot create

or destroy the energy pre-existing in the two waves, but it can (and often does) redistribute the energy according to the conservation of energy principle. If the total energy in the two superposed waves is different from the sum of the two energy components before superposition, then interference exists and some interference energy has been redistributed in the system. That some people are ignorant of where the constructive interference energy came from or where the destructive interference energy went is not a good reason to deny its existence (which violates the accepted laws of physics).

The thing that makes an interference event so easy to analyze in a transmission line is the fact that the transmission line is essentially one-dimensional. At an impedance discontinuity in a transmission line (away from any active source) if interference exists, the destructive interference in one direction must equal the constructive interference in the other direction. Any other outcome would violate the conservation of energy principle and that is a common occurence on this newsgroup.

In my earlier example, the two results of *(1) reflection* are traveling waves containing ExH power densities:

Pfor1(rho^2) toward the source and

Pref2(rho^2) toward the load

The complimentary transmissions are:

Pfor1(1-rho^2) toward the load and

Pref2(1-rho^2) toward the source

Those two reflections *(2) superpose* with the two complimentary transmissions in each same direction according to the power density equation:

0 = Pref1 = Pfor1(rho^2) + Pref2(1-rho^2) minus total destructive interference toward the source

Pfor2 = Pfor1(1-rho^2) + Pref2(rho^2) plus constructive interference toward the load

When one assumes that reflection is the only phenomenon that can redistribute wave energy, one is ignoring the superposition process which is also known to be perfectly capable of redistributing wave energy. In Roy's food-for-thought example, he designed it so reflections would not exist at the source. That leaves superposition as the phenomenon that is accomplishing the obvious redistribution of energy. It certainly does NOT mean that the laws of physics have been suspended due to the ignorance of the writer.

Here's a simple exercise in phasor superposition. Given two 50w (joules/sec) coherent EM waves traveling in the same direction in Z0=50 ohm coax:

1. What is the magnitude of the two voltages? ________

2. If one superposes those two voltages in phase in the Z0=50 ohm transmission line, what is the resulting power (joules/sec) in the total wave? ___________

3. If one superposes those two voltages 180 degrees out of phase in the Z0=50 ohm transmission line, what is the resulting power (joules/sec) in the total wave? ____________

In #2, if there is no source around, where does the "extra" wave energy come from?

In #3, if there is no source or sink around, where does the "excess" wave energy go?

> Can you explain how the “reflected power” “knows”?

Reflected "power" doesn't know anything. Reflected voltages and
currents simply respond to the known laws of physics involving wave
reflection and wave superposition, and obey the conservation of energy
principle.

In 1, it doesn't stay out of the generator. It is redistributed from
the generator back toward the load by superposition associated with
*destructive interference) which happens when two superposed coherent
waves are between 90 deg and 180 deg out of phase. The entire
experiment is set up in a perfect 50 ohm environment so power =
V^2/50. What you guys are missing is that step which carries the
energy along with the voltage, i.e. the voltage (and current) require
a certain energy level which is being ignored.

In 2, the source wave never encounters the reflected wave so there is
no superposition or interference at the source resistor.

You can add a couple of more configurations. Number 3 could be when
the interference between the source wave and the reflected wave occurs
and they are less than 90 deg out of phase. More power than the
average reflected power plus average load power will be dissipated in
the source resistor because of superposition associated with
constructive interference.

Number 4 could be the special case when the source wave and the
reflected wave are 90 degrees out of phase. This is the condition of
zero interference (neither destructive nor constructive) and 100% of
the average reflected power is dissipated in the source resistor. This
is the easiest case to understand because there are no reflections and
no interference.

I've seen essentially the same ... bigger than 1/2 (or 5/8) wavelength works well. BUT... that's for a "good match".. if you're willing to tolerate a "not so good match" I think you can get much shorter.

There's a lot of antenna designs that use this sort of scheme to match, say the 100 ohm impedance of a helix to 50 ohms, over a distance on the order of 1/4 or 1/5 wavelength. Whether it's truly a tapered transmission line or a semi-distributed lumped L and C is probably a good question. Certainly, one could use a string of lumped L/C networks to make a synthetic transmission line that has mechanical length much shorter than 1/2 wavelength. So, when does a series of lumped LCs become a transmission line?

You also see tapered transitions in microstripline all the time, and they're often shorter than 1/2 wavelength. But maybe that's more in the nature of a "distributed matching network" rather than a pure transmission line.

There's a goodly amount of empiricism in both antennas and stripline design. Especially if you're talking about an balanced pair with separation smaller than the diameter/width of the conductor, it's probably not a "simple" transmission line.

2693. Re: Tapering open wire feedlines?

Source record: 8793

I saw hints that the application of the tapered line matching section was to a HF off centre fed dipole, and an assumption that as a multiband antenna, it had a feedpoint impedance of close to 200+j0.

Most users of OCF dipole systems are expecting to be able to use the antenna on many bands without an ATU, and accept significant tradeoffs in peformance for that objective.

It is unlikely that the feedpoint impedance of the dipole itself is sufficiently tight to worry too much about the broaband peformance of a tapered line matching section, much less the practicality of constructing low loss tapered two wire lines with Zo approaching 50 ohms.

It is only when a system perspective is taken, that some of the component level discussion seems to be an interesting issue, but poor application.

Owen

well, it works as they say it will only go a few inches because the
antenna is probably only a couple inches long at some low frequency...
once you give it a decent antenna it will work much better.

Having built one of these things or very similar (or more properly, my
tween daughter did)..

Hook a 6-10 foot long piece of wire to each of the clips and stretch
them out and it works pretty well. In my case, we threw a hunk
(precision measurement.. probably about 10 ft) of wire over the curtain
rod, and laid the other one out across the floor, transmitter sitting on
the desk. You could receive it on a standard AM BC radio with a ferrite
loopstick antenna at the other end of the house, some 15m/50 ft away.

The idea of using a 1MHz clock oscillator *is* clever. Back in the day,
I would have lashed up something with a single transistor and a LC tank.

BTW, the same general idea works pretty well with a 14.318 MHz
oscillator.. A 1 meter antenna makes a fine beacon signal right in the
20m band. Of course, you'll ID, operate within your license terms, etc.
In theory, if you could get it to swing 5V, you could put a couple

hundred milliwatts into a dipole, but I don't think they have that much drive available.

I confess I haven't tried AM with the 14.318 oscillator..It probably has some non-zero frequency pulling too.

The "other one out across the floor" works as the chassis.
The chassis is enough for the small power at higher frequencies.
Your phone cell has the chssis (ground) also.

" Transmitters for long and medium wave require good grounding and soil of
high electrical conductivity. Locations at the sea or in river valleys are
ideal, but the flood danger must be considered. Transmitters for UHF are
best on high mountains to improve the range ".

So I look here: http://en.wikipedia.org/wiki/Warsaw_radio_mast

"This technique works by applying a DC ground at a point of minimum
radiofrequency voltage, conducting static charge to ground without
diminishing the radio energy. Static electrical charge can build up to high
values, even at times of no thunderstorm activity, when such tall structures
are insulated from ground."

Would be interesting to know the value of the DC current.

Do you agree that it is the field emission (loss of electrons)?

No.. it's plain old corona discharge or triboelectric charging from
particulates

loss of electrons maybe, but due to friction with particulates in the
atmosphere. also partly due to the fair weather electric field:

What does HT mean in "HT radio"

What do the 2 letters stand for?

Obviously the expression describes hand held radios,
but I cannot find an explanation.

thanks,
w.

"Handie-Talkie" (or variations on the spelling thereof).

This was originally a brand-name term for the Galvin (think
"Motorola") SCR536 portable radio, introduced in 1940. The
abbreviation "HT" has since been co-opted by hams (and perhaps others)
to refer to almost any hand-held portable UHF/VHF radio.

Motorola offered commercial handheld radios with model numbers of
"HT200" and "HT220" (and certainly others) that were easily modified for
operation in the 2 meter and 450MHz ham bands and were quite popular in
the early 1970s.

Also, CB's used walkie talkies, and Hams used handy talkies.

Or at least that's the way it was explained to me.

Dear Cecil:

I understand you proposition about energy redistribution on reflections and constructive/destructive interference phenomena. It is easy to me understand tridimensional waves examples interfering on a surface, rendering strips of nulls and maximuns. In a TL I also understand interference must render -for example- a destructive composition towar one direction and a constructive towards opposite direction. Full destructive interference in one directions implies full constructive on the opposite one, rendering a unidirectional energy flow towards the constructive direction, and zero flow toward the other. However I can not visualize a simple mechanism to generate such system in a TL. Tridimensional examples are easily because RF or light source can be set very close to each other as in physics traditional ligth examples and render the interference pattern, but in a TL they need be in the same place: I managed to explain my idea? Give me a hand. (It is a pitty newsgroups do not have image capabilities)

I am studying your paper published in World Radio Oct 2005. Have you a demonstration of the equation cited fro "Optics" book => Pfor=Pi +P2+2[sqrt(P1P2)]cos(theta)?

While Handy-Talky was probably the most used brand name that Galvin used,
Motorola was so popular that they renamed the company to it.

In the airplanes is the "chassis ground". The large metal surface is the
charge source. The surface exchanges charges with the air.

In a short period of time the atmospheric conditions are similar.

I am asking for measurement of the netto current in the track
ground-antenna.
The two measurements: before and during transmitting in the same atmospheric
conditions.

"Static electrical charge can build up to high values".

It take place during transmmiting.
Without grounding do not work.

I simply want to know "the value of the DC current".

Do you know it in your station?

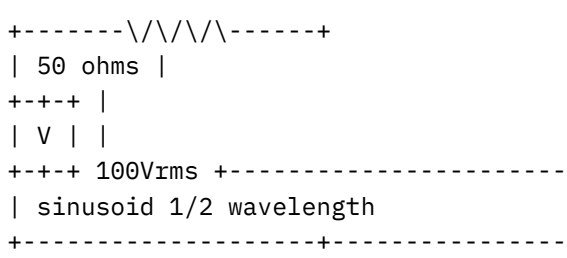
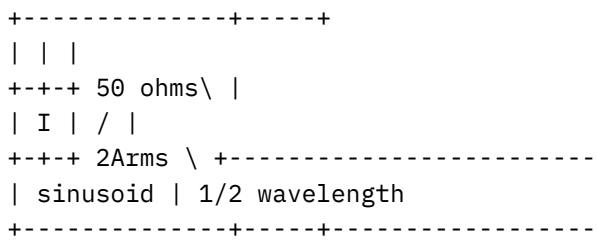
Continuing with experiment 1 and recalling its description:
- a sinusoidal generator that will produce 50W in to 50 ohms
- attach one half wavelength of transmission line
- leave the far end of the transmission line open
- the generator is constructed in the Thevenin style with a
voltage source and 50 ohm resistor
for greater certainty we can draw a schematic:



The result, as before, is 50W “reflected power”, 0W supplied by
the source and 0W dissipated in the source resistor. This you
explain as “redistribution towards the load by superposition
associated with destructive interference”.

Short the end of the transmission line. Now 100W is dissipated in the source resistor, but there is still 50W of “reflected power”. I assume you will suggest there is now “constructive interference”.

Replace the generator with one constructed in the Norton style:

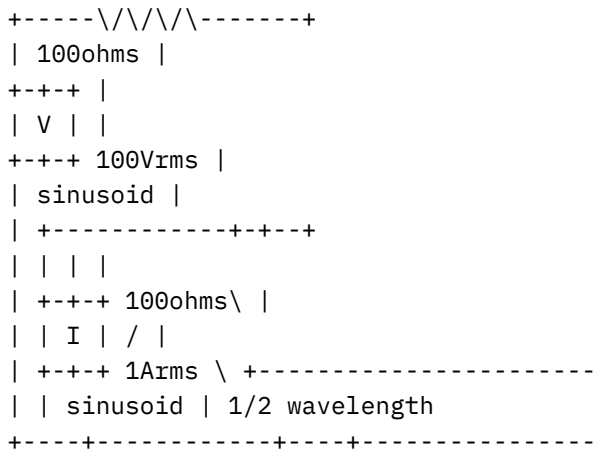


Now, as before, there is 50W “reflected power”, but the source is supplying 100W and the source resistor is dissipating 100W.

I assume you will claim that there is now “constructive interference” rather than the previous “destructive interference”, but the line conditions are the same. How does the “reflected power” know if it should construct or destroy? The phase is the same.

Apply the short at the end of the line. 0W are now dissipated in the source. “Destructive interference”? For some reason? The line conditions are the same.

Consider a generator constructed as below:



This generator has the interesting property that the power provided by the sources is constant at 100W, regardless of load.

The sources are supplying 100W, the source resistors are dissipating 100W, and the same 50W of “reflected energy” is “flowing” on the line.

Apply the short. 100W is being dissipated in the source. The line conditions are the same.

For this generator, the phase of the reflection does not appear to affect the kind of interference. Hmmm.

Now for each of the above experiments, remove the transmission line and attach the load directly to the generator output. In all cases the generator behaviour will be the same regardless of whether the half-wavelength line is present or not.

So it still seems to me that the accounting is much more dependant on the generator construction and the load applied to the generator terminals than it is on the presence of “reflected power” and constructive or destructive interference.

This equation is problematic. Firstly, it mixes power with voltage
since
theta is the angle between the voltage waveforms. As K1TTT said, "why
not just do the whole thing with voltages?" This mixing is bad form
and
clearly demonstrates the incompleteness of the power based analysis.

The second is that there are two solutions depending on whether the
positive or negative root is used? Why is one discarded? Is this
numerology at work?

Thirdly, it only produces the correct answer for average energy flows.
If the instantaneous energy flows are examined, the results using
this
equation do not align with observations.

> However I can not visualize a simple mechanism to generate
> such system in a TL.

I have given the equations for what happens at an impedance discontinuity in a transmission line. The s-parameter equations are the same equations in a different format. Simply visualize the voltage phasors resulting from reflections-from and transmissions-through the impedance discontinuity. Let's start with voltages instead of power.

source------Z01=50 ohms------+------Z02=300 ohms--------load

measured Vfor1 = 50v, Vref1 = 0v
calculated rho1 = (300-50)/(300+50) = 0.7143

Vfor1*rho1 = 35.7v at zero degrees = portion of Vfor1 reflected by the impedance discontinuity at '+'.

Vref2*tau2 = 35.7v at 180 degrees = portion of Vref2 transmitted back through the impedance discontinuity at '+'.

Vref1 = Vfor*rho1 + Vref2*tau2 = 0, measured Vref1. This is the same as the s-parameter equation (1).

b1 = s11*a1 + s12*a2, all phasor math

These are the two voltage components that superpose to zero volts. Both of those wavefronts are phasors with phase angles referenced to the Vfor1 phase angle.

Now let's look at the power in the component phasor wavefronts.

(Vfor1)^2/Z01 = 50^2/50 = 50w, power in the Vfor1 forward wave

(Vref1)^2/Z01 = 0^2/50 = 0w, power in the Vref1 reflected wave

(Vfor1*rho1)^2/Z01 = 35.7^2/50 = 25.49w

(Vref2*tau2)^2/Z01 = 35.7^2/50 = 25.49w

Pref1 = 25.49w + 25.49w + 2*SQRT(25.49*25.49)cos(180)

The corresponding s-parameter power equation is:

b1^2 = (s11*a1 + s12*a2)^2

b1^2 = (s11*a1)^2 + (s12*a2)^2 + 2(s11*a1)(s12*a2)

The two wavefronts that cancel toward the source contain energy before they superpose to zero. Where does that energy go? Superposing to zero

indicates total destructive interference toward the source. The conservation of energy principle says that energy cannot be destroyed so it must appear as an equal magnitude of constructive interference in the only other direction possible, i.e. toward the load.

The above equations deal only with the destructive interference toward the source. There is a second complimentary set of voltage/energy equations that deal with constructive interference toward the load.

> same.

That's easy to answer. The Norton equivalent is a current source so currents should be used in the calculations. The phase angles between the two current components are 180 degrees different from the phase angles between the two voltage components. If the interference between voltages is constructive, the interference between currents will be destructive. Hint: the reflected current phasor is 180 degrees out of phase with the reflected voltage phasor because of the direction of travel of the reflected wave. As a result of directional convention, the power in the reflected wave is negative.

So destructive interference for forward/reverse voltages is constructive interference for forward/reverse currents and vice versa. An SWR voltage maximum (constructive voltage interference) is an SWR current minimum (destructive current interference) and an SWR voltage minimum (destructive current interference) is an SWR current maximum (constructive voltage interference).

> This equation is problematic. Firstly, it mixes power with voltage
> since theta is the angle between the voltage waveforms.

You apparently don't understand what happens when one takes the dot product of two voltage phasors (and divides by Z0). The result is watts but the math involves the cosine of the angle between the two voltage phasors. All competent EEs should already know that.

> As K1TTT said, "why not just do the whole thing with voltages?"

Because the title of this thread is: "What happens to reflected energy?", not what happens to reflected voltages? Doing the whole thing with voltages allows the obfuscation of interference to be swept under the rug.

Because some of you guys don't recognize interference when it is staring you in face? I was taught to recognize interference between voltage phasors at Texas A&M in the 1950s. What happened to you guys? Here's a short lesson about dot products of voltage phasors and the resulting interference between the two voltages.

Vtot = V1*V2

Vtot^2 = (V1*V2)^2

Vtot^2/Z0 watts = (V1*V2)^2/Z0 watts

There will be the two obvious power terms, V1^2/Z0 and V2^2/Z0, representing the powers in the individual waves before superposition. There will be a third, additional interference term whose dimension is watts that *requires the dot product* between the two phasor voltages. Therefore, your objection is apparently just based on ignorance of the dot product of two voltage phasors.

> This mixing is bad form and
> clearly demonstrates the incompleteness of the power based analysis.

Good grief! This "bad form" has been honored in the field of optical physics for at least a century. It was taught in EE courses 60 years ago. I don't know what has happened in the meantime. Walter Maxwell explains interference in section 4.3 in "Reflections" and obviously understands the role of interference in the redistribution of energy.

> The second is that there are two solutions depending on whether the
> positive or negative root is used? Why is one discarded? Is this
> numerology at work?

Negative power is just a convention for "negative" direction of energy flow. All EEs are taught in our engineering courses to ignore the imiginary root when calculating resistance, energy, or power.

For instance, the Z0 for the 1/4WL matching section between R1 and R2 needs to be SQRT(R1*R2). When you perform that math function, do you really go on a world-wide search demanding a transmssion line with a negative Z0? Please get real.

> Thirdly, it only produces the correct answer for average energy flows.
> If the instantaneous energy flows are examined, the results using
> this equation do not align with observations.

You forgot to add that instantaneous energy is as useless as tits on a boar hog, or as Hecht said, putting it mildly: "of limited utility". It appears to me that instantaneous energy is just a mathematical artifact inside a process requiring integration in order to bear any resemblence to reality. Omit the integration and the process loses touch with reality. Instantaneous energy has zero area under the curve until the intergration process has been performed. A zero area represents zero energy. Otherwise, when you integrate from zero to infinity, the result would be infinite energy.

Do you have any kind of reference for your treatment of instantaneous power?

The physical mechanism is the Z01==>Z02 impedance discontinuity with
its associated reflection coefficient, rho. We can see that reflection
on a TDR so it is indeed a PHYSICAL mechanism.

Sorry, I lost my train-of-thought here and changed horses in mid-
stream. All I was trying to illustrate is that the dot product of two
voltage phasors divided by Z0 has the dimensions of watts and contains
the cos(A) term. Again, my apology for wandering off the logical path.

Would that be the so-called "fair weather current" about 1 pA/square meter?

Obviously, a big metal tower is going to perturb the local field, so a
tower with a cross section of 1 square meter is going to have a current
a lot bigger than 1pA.

But probably not microamps.

OTOH, a big tower could have substantial capacitance to ground.. I don't
recall off hand what the capacitance of a isolated cylinder is..
I seem to recall that for a rod with length>>diameter, it's something
like 50pF/meter.

So, a 100 m tower will be 5000 pF.

Say the current is 1000 pA.

In one second, the voltage would be 1E-9/5E-9 = 0.2V

In a minute, 30V
In 10 minutes, 300V..

etc

Probably not enough to charge to voltages quickly enough to be a problem.

Tribocharging from dust and other particulates blowing in the wind is a
LOT faster and a bigger problem.

don't forget the OTHER physical mechanism that is necessary,
superposition... the ability to add voltages, currents, and fields in
linear circuits and media.

He has yet to wonder how satellites could transmit very long. After
all, there would come a point in time where the charge would be so high
on the vacuum insulated satellite that it could perform his field
emission any longer.

It should be easy to observe as the signal strength would decrease with
time. I haven't noticed that effect myself, nor has anyone else.

Very inventive. And the wave just knows the difference between the
50ohm
generator that is constructed in the Thevenin style and the 50ohm
generator constructed in the Norton style. Amazing waves.

And now the explanation for the mixed constant power mixed Thevenin/
Norton
generator is ...?

Still does not explain why you choose only the positive root.
Especially when you let the result be negative as a consequence
of cos(theta).

I always get a chuckle when you write this. It makes me think of a
kid,
who, upon being told that he can not have his favourite dessert until
he finishes his brussel sprouts, declares that he has always hated
that dessert.

You might study why the real power folk prefer three phase to single.
It all has to do with instantaneous power.

Might not make a difference for light, but it sure helps the
understanding at RF and lower.

And your analysis still only produces the correct answers for the
average and still gets the instantaneous wrong. I do see the benefit
of repeating "of limited utility".

As I suggested above, have a look at the benefit of three phase over single.

Hello Cecil. I will try another translation because I think I could
not explain well my question.
We can see energy maximuns and nulls with simple experiments with
light. We set a double slits experiment and we see light flowing in
same direction reinforcing and cancellating in maximuns and minimuns
on screen. You name it "redistribution", the energy "dissapearing"
from nulls reappears on maximuns (Sorry, I use this horrifying light
example too because physics books have such unhealthy trend to explain
wave interference)
In a TL, instead, total destructive interference in one point would
mean energy stop flowing from that point forwards (is it OK say
"forwards"?) and reverse its flow direction doubling his value, is it
OK?. You name it "redistribution" too, not reflection. Well, my
question was how we can set (devise) an experiment to get such
behaviour in a TL? We need add (or put) in this point a source of
energy to make the interference (the second slit light source from the
light example, or the other front wave in a diffraction example), how
to, here?. Light experiments is easy because we put both independent
coherent light sources near each other illuminating the screen but
here I can not visualize how put them. I hope I was explain better my
question.

Are you sure?
Each ground must be large enough. Engineers know what to do.
Sometimes they water the ground area.

In the space the chassis must be large enough.

I mentioned same comment in another post. We use superposition
principle in two different contexts. Superposition theorem in circuit
theory, and wave superposition. Wave (traveling) superposition deals
with f(t,x,y,z) and usually with puntual magnitudes, E, H, D, B, etc)
while circuit theory deals with a subset f(t) phenomena and with
integrated magnitudes (V, I). Sometimes that becomes a confused
issue :)

NO, superposition is always the same. it is the linear addition of
currents or fields in a linear media. it works the same for circuits
as for em waves.

the big problem are the people who confuse the formulas for adding
powers with adding fields or currents/voltages and forget the phase
terms.

the other big problem is keith who seems to want to separate his waves
into separate time and space variables and leaves out the requirement
that wave functions must be dependent on both space AND time.

basically any solution to the wave equations derived from maxwell's laws must be of the form f(t-x/v). this leads him to the erroneous conclusions he gets from trying to compare his batteries to wave propagation. this is the same problem people have with standing waves, they have separate dependence on t and x, so they can't travel and can't transport energy.

you are almost as much fun as art with his magical levitating
neutrinos.

no, i have antennas that are isolated from ground. they are fed
through a capacitor that prevents the charge from flowing to ground
and they do not get charged over time. i know this because when a
thunderstorm is nearby they build up enough charge to arc over the
capacitor. if there was charge being constantly emitted when they are
transmitting the capacitor would arc all the time.

Repeating myself - it is not necessary for you to imagine magical smart waves. Ignorant people invent magic and metaphysics to explain away their ignorance. All you need to do is to alleviate your ignorance concerning the laws of physics which those ordinary EM waves are obeying. *Externally*, it doesn't matter whether you use voltage superposition, current superposition, or EM field superposition - the results are identical. Every EE professor I ever had warned me about trying to look inside a Thevenin or Norton source at the power dissipation in the source resistor. For instance, their internal dissipations are exactly opposite for shorts and opens so exactly why should you expect the internal interference levels to be the same? When the Thevenin source is dissipating all the power inside the source from being connected to a *short-circuit*, it is experiencing total constructive interference. When the Norton source is dissipating all the power inside the source from being connected to an *open-circuit*, it is experiencing total constructive interference - opposite external conditions causing exactly the same phenomenon inside the two source boxes.

> And now the explanation for the mixed constant power mixed Thevenin/
> Norton generator is ...?

Neither the Thevenin equivalent source nor the Notron equivalent source is "constant power". The Thevenin equivalent source is a constant voltage source with a series source resistor and the Norton equivalent source is a constant current source with a shunt source resistor. A constant power source is conceivable but it would either need a circulator plus load, have a pretty sophisticated feedback system, or be driving an ideal instantaneous antenna tuner.

Of course it does. In the power density equation, choosing the
negative root would lead to a violation of the conservation of energy
principle. When one of the roots is obviously impossible in reality, a
rational person chooses the other root.

> You might study why the real power folk prefer three phase to single.
> It all has to do with instantaneous power.

I am a "real power folk", Keith. My first EE degree was in power
generation and transmission. Three-phase puts less stress on the
system by eliminating the hills and valleys in the energy flow common
with traveling waves. But why do you believe that three-phase power
transmission is relevant to ham radio? Are you running three-phase RF?

Maxwell's equations don't even work for your mashed-potatoes version
of energy. That should tell you something.

> But then what explains the reflection at the generator that presents
> Z0 to the line?

Your error is in assuming it is a reflection. It is NOT a reflection which, by definition, involves one wave. It is a redistribution of energy due to superposition which, by definition, involves two or more waves. In a system designed to eliminate reflections at the source, ALL of the redistribution of reflected energy back toward the load is due to superposition accompanied by interference. From the FSU web site:

"... when two waves of equal amplitude and wavelength that are 180-degrees ... out of phase with each other meet, they are not actually annihilated, ... All of the ... energy present in these waves must somehow be recovered or redistributed in a new direction, according to the law of energy conservation ..."

Nothing said about *reflection* (involving a single wave). It is all about the meeting (superposition) of two waves which can cause the redistribution of energy. It may look somewhat like a reflection but it is technically NOT a reflection.

In our ham transmission line systems, the goal is to accomplish total destructive interference toward the source, i.e. zero reflected energy incident upon the source. So let's talk about destructive interference toward the source and constructive interference toward the load.

> You name it "redistribution" too, not reflection.

By definition, reflection is something that happens to a single wave. By definition, superposition involves two or more waves. The redistribution that I am talking about can include both reflection and superposition if both are present. Depending upon the system configuration, both may be present, both may be absent, or one exist without the other.

> Well, my
> question was how we can set (devise) an experiment to get such
> behaviour in a TL?

I've presented it before and it is a simple Z0-match involving a 1/4WL matching section.

50w-----50 ohm------+------1/4WL 300 ohm------1800 ohm load

On the source side, rho at '+' is 0.7143

Using a TDR, we can verify that there is indeed a reflection from the 50/300 ohm impedance discontinuity. What happens to that reflection during steady-state?

What happens to Vfor1(rho) = 50v(0.7143) = 35.7v?

What happens to Pfor1(rho^2) = 50w(0.51) = 25.5w?

Your station produces asymetrical pulses. The all real waves are not
symmetrical. The insulator in the capacitor is a poor conductor but its
surface is large.
It CONDUCTS because the pulses are not symmetrical.

>and they do not get charged over time.

They must: " In electronic circuit theory, a "ground" is usually idealized
as an
infinite source or sink for charge, which can absorb an unlimited amount of
current without changing its potential."

The electronic circuit theory is the ruler in your station. Not EM.

Your capacitor is fit to transmitting not for lightnings.

>Your error is in assuming it is a reflection. It is NOT a reflection
which, by definition, involves one wave. It is a redistribution of
energy due to superposition which, by definition, involves two or more
waves. In a system designed to eliminate reflections at the source,
ALL of the redistribution of reflected energy back toward the load is
due to superposition accompanied by interference. From the FSU web
site:

>"... when two waves of equal amplitude and wavelength that are 180-
degrees ... out of phase with each other meet, they are not actually
annihilated, ... All of the ... energy present in these waves must
somehow be recovered or redistributed in a new direction, according to
the law of energy conservation ..."

>Nothing said about *reflection* (involving a single wave). It is all
about the meeting (superposition) of two waves which can cause the
redistribution of energy. It may look somewhat like a reflection but
it is technically NOT a reflection.

In the Hertz dipole the reflection take place but in the loop antenna "two
waves of equal amplitude and wavelength that are 180-degrees ... out of
phase with each other meet,"

But the both cases are the same. At the meeting the energy is radiated and
the electrons emitted because in the meeting place the voltage is doubled.

The electronic circuit theory do not use EM.

I did not say that things were fundamentally different, I said "context" it is different, as "substraction" in mathematics, you can not subtract a natural number bigger from a smaller one in natural field, but you can do it in integer field, we have to apply (comply?) contextual rules with such operations. Otherwise I agree with what you say. 73

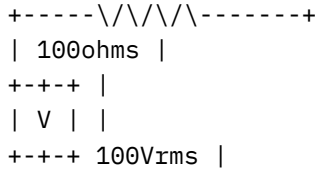
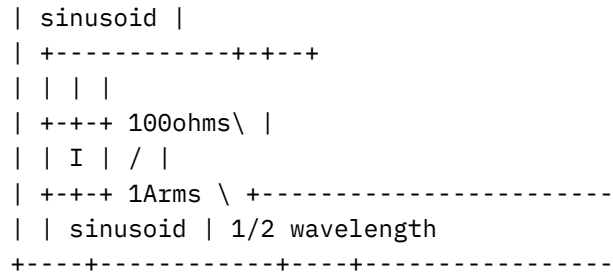
You should study the design of the generator described previously and
repeated below, for your convenience:





As I said, this generator has the interesting property that the power provided by the sources is constant at 100W, regardless of load.

Can you make your redistribution explanation work for this one?

Using superposition, when you add Vrev2(tau) to Vfor1(rho) you get
zero.
With zero voltage comes 0 energy transfer.

For further learning, do not just examine steady state, but also
examine

how it gets to steady state. Using a lattice diagram, examine what happens as the first reflection and then each re-reflection arrives at '+'. Determine how Vrev2(tau) slowly builds to equal Vrev1 and cancels it, using the simple addition of superposition. While this process is occurring, there is a Vrev1 which decreases after each round trip in the second line section.

This is all done with simple addition. No need for products and square roots.

For further marks, decide whether you should think of Vrev2 as an infinite sum of reverse waves or is it okay to think of it as one sum that slowly accumulates.
Which is it really?

Same question for Vfor2.

> What happens to Pfor1(rho^2) = 50w(0.51) = 25.5w?

Once you have computed total Vrev1 using simple superposition, it is easy to compute that the "reverse power", Prev1, is 0.

Do you really need rho^2 to understand what goes on in a transmission line?

I see that the stress induced by considering DC waves is causing you
to misinterpret my writings.

May I suggest an alternate exploration for you. Assuming that you
accept TDR and know how to use Reflection Coefficients to compute
voltage and current reflections, then consider what happens
when a rectangular pulse is launched from a matched generator in
to a transmission line. For simple reflection coefficients like
0, 1, and -1 compute the reflected pulse. For both the forward
and reflected direction compute the voltage and current on the line
before the pulse arrives, as it passes and after it has passed.

Compute the energy in the pulse, and how long a distance it
occupies on the transmission line. Compute the power as the
pulse is passing.

Be sure you know what happens to the pulse when it re-enters
the generator. For simplicity, assume a generator constructed
using the Thevenin circuit.

Make sure all the results are in agreement; especially, the
energy delived by the source and the energy dissipated in the
various resistors.

Now make the pulse longer and longer... until it looks like
a step function. And do the computations again.

Determine if the results agree with those I previously
presented for the DC example.

...Keith

Your mistake here is to assume that because they can sink current that
the are sinking DC current. The "ground", as you like to think about it
may carry current during the RF cycle, but there is nothing that would
cause an unbalanced charge buildup since it IS symmetrical.

You know, he is sort of more amusing than Art. At first. Art can argue
and Art makes no sense, and neither does Szechuan, but he can't build an
argument that even sounds a little bit logical. And his arguments never
change. Art makes up new stuff all the time.

Prediction - Szechuan will eventually become so boring no one that no
one will respond.

Your mistake here is to assume that the RF cycle, IS symmetrical.

Each real wave is asymmetrical. The forward pulse is always stronger than
the return.
For this reason you must have power on.

Each one of you can measure the DC ground current.
Why you are so boring sending the same incontructive answer (no emission).
Emission is a fact. It is interesting how it is much.

why would i want to do all that work? there is no way that my answers
will agree with your misconceptions. you'll just come up with an even
uglier generator to try to make it fit.

oh, and by the way, your fancy 2 generator and 2 resistor 'constant power' source isn't what you think it is. go back to basic circuits 101 and you will find that any linear network like that can be reduced to either a simple one source one impedance norton or thevenin equivalent. in your example it is identical to a 50v voltage source in series with a 50ohm resistor... deriving the norton equivalent is left for the student.

first, the fcc would get really mad at me if my rf waves weren't
symmetric, that would make for horribly distorted signals!

and yes, i have measured the dc ground current and it is also zero.
when you have a transmitter in your car are the rubber tires not
isolating the car body from ground? do you get shocked after you have
been transmitting for a while and step out of your car? where does
the ground current go when you have a plastic cased handheld radio?

i agree, mr. b is not as much fun as art... at least he made up things
that weren't so easy to observe as wrong, after all who could see the
waste deep levitating neutrinos jumping off their diamagnetic
antennas. mr. b's stuff is just absurd.

On Jun 25, 4:00 pm, Keith Dysart <keith.dys...@gmail.com> wrote:
> That's the time domain. Variation in the instantaneous energy flow.

What you seem to be missing is that the *energy content* of power (total joules) must be conserved but the instantaneous power (joules/second) does not have to be conserved as you have argued numerous times in numerous examples. The only question that needs to be answered is: In a system designed to eliminate reflections and interference, does all the reflected energy eventually get dissipated in the source resistor. The answer is yes because there is nowhere else for it to go. There is no conservation of power principle and that includes instantaneous power. So it is irrelevant what/where instantaneous power might do/go during a single cycle.

Now I understand that instantaneous power dictates some physical design considerations as in waveguides. But since instantaneous power does not fall under the conservation of energy principle, it is simply irrelevant to the present discussion. What happens over a complete cycle is what is relevant. However, in any and every case, it is energy that is conserved, not power. How many joules are in that dt sliver of time when the instantaneous power is 100 watts? It's those joules that must be conserved, not the instantaneous power.

You didn't answer my previous question. If you measure 100 watts of instantaneous power at 100 places within an inch of each other, does that mean there is 10000 watts of instantaneous power in that one inch of wire? That is the only logical conclusion based on your argument and assertions. Any argument based on the conservation of power is doomed to fail. Please get real.

> Not quite
> 'as useless as tits on a boar hog, or as Hecht said, putting it
> mildly: "of limited utility"'.

One could argue that tits on a boar hog are not completely useless and, therefore, instantaneous energy is exactly as useless (or exactly as useful) as tits on a boar hog. (Hint: Without the existence of the tit gene in the male, female hogs would probably not have tits.)

Nobody except you, using instantaneous power, has attempted to
superpose power. The Power-Density/Interference equation does NOT
superpose power because it contains the interference term. If the
interference term were omitted than it would be an attempt to
superpose power, but I have never omitted the interference term except
when it was zero.

> Using superposition, when you add Vrev2(tau) to Vfor1(rho) you get
> zero. With zero voltage comes 0 energy transfer.

Completing your above sentence: With zero voltage comes 0 energy transfer *in the direction of travel of the original waves that were superposed*. Assuming that you believe in the conservation of energy principle, what happened to the energy in the two component voltage waves necessary for their existence before they cancel each other? If they didn't contain any energy, they would be zero but we know they are not zero, i.e. they are 35.7 volts each. That original wave energy is redistributed and *transfered* in the opposite direction, the only other direction available in a transmission line.

One cannot argue with a forked tongue that the superposed waves never existed in the first place because that would violate the laws of physics and superposition.

> Do you really need rho^2 to understand what goes on in a transmission
> line?

Not using rho^2 is why you are so confused. If you actually cared where the energy goes, you would be forced to use rho^2 or at least multiply the superposition component voltages and currents to obtain the power in the superposition component wavefronts.

In the earlier example, the impedance discontinuity has a physical voltage reflection coefficient of 0.7143 and a physical power reflection coefficient of 0.51. If you consider the steady-state power conditions, you will calculate a virtual power reflection coefficient of 0.0 and a virtual voltage reflection coefficient of 0.0. Which reflection coefficient is correct? Obviously, physical trumps virtual every time.

The 50v source voltage reflected at the 0.7143 reflection coefficient is 35.7 volts and it exists in a 50 ohm environment. Simple math yields the power = (35.7)^2/50 = 25.5 watts. Where did the energy in that 25.5 watt EM wave go? One can obtain the same value by calculating the current: 1a(0.7143) = 0.7143. Power = 35.7(0.7143) = 25.5 watts.

So you can get by without using rho^2 but to determine where the energy is going, one needs to at least multiply the EM traveling-wave voltage by the EM traveling-wave current (or calculate the ExH Poynting vectors).

In fact, this would be a good application for your instantaneous power calculations. Where is the energy going that is in the instantaneous power being reflected by the impedance discontinuity?

when you have a transmitter in your car are the rubber tires not
isolating the car body from ground?

You do not read my posts:
""The use of the term ground (or earth) is so common in electrical and
electronics applications that circuits in portable electronic devices such
as cell phones and media players as well as circuits in vehicles such as
ships, aircraft, and spacecraft may be spoken of as having a "ground"
connection without any actual connection to the Earth. This is usually a
large conductor attached to one side of the power supply (such as the
"ground plane" on a printed circuit board) which serves as the common return
path for current from many different components in the circuit."

>do you get shocked after you have
been transmitting for a while and step out of your car?

It is common event.

In the radio area it is nothing to do.
Everything was done by Stokes, Helmholtz and Tesla.
Radio people should know a little about them.

The first step should be measuring the DC ground current.

that quote is correct... unfortunately the voltages created by most
radio transmitters aren't high enough to overcome the metal work
function so no field emission takes place from antennas. and even if
it did it wouldn't go anywhere because radio waves are symmetric.

2773. language and antenna gain

Newsgroup: rec.radio.amateur.antenna
Date: 2010-06-27 14:09:09 UTC
From: "-.-. --.-" <a@a.com>
Message-ID: <i07m1l$2k0$1@speranza.aioe.org>
Source record: 8573

All begin reading the advice of a reseller on a Italian ham magazine, that claim this (translated):

"The MFJ 1796 antenna only at XXX euro !!! 2,6,10,15,20,40 meters Superior Half-Wave configuration !!"

Oh well, i'm really a rookie on antenna theory, but - thinking into myself - someone at MFJ can please explain me what the hell make on this antenna to shrink an half wave antenna on 40 meters into a stick shorter than quarter wave??

Before posting the question on this NG to learn more, a look on MFJ site and i read on the description:
"Full size halfwave on 2/6 Meters."
Ah right, someone here in Italy forget to specify *where* is 1/2 wl designed :)
But the funny thing is not what i tell until now... the funny (or sadly) thing is that 7 local hams over 10, asking them if on 40 meters perform well the MFJ 1796 or a common quarter wave antenna, reply "the 1796 for sure ! Is a half wave designed antenna" someone adding also " you know antenna theory, not ??"
Of the remaining 3 hams, 2 of this 3 replied with approximately my same doubt ("what?? an half what ??")
A special mention to the last one that replied the dipole is the only antenna that he consider. He said that vertical antenna is the best system to deliver half or more applied power to the earth, no matter how is designed. So he don't ever read the advice and don't reply to the original question :)
...
Well, marketing and language misuse can add gain on an antenna, now i know this :)

Sorry for my english, i hope that the sense of the story is clear to readers.

I previously had a senior moment and changed contexts in the middle of
a posting and I apologize for any confusion. Would you enlighten me as
to the area of the discussion that you don't catch? Do you understand
physical reflection and transmission coefficients and their effect on
voltage, current, and power?

It would be an opportunity for you to deepen your understanding of the behaviour of transmission lines.

> there is no way that my answers will agree with your misconceptions.

I am not convinced. You have not yet found any errors in my expositions,
so if you do not make any errors, I expect we will agree on the outcome,
though perhaps not on the interpretation, for you disagree when I say "do not assign TOO much reality to the energy in reflected waves.

You seem to want your reflected waves to always transport energy, but are unhappy that this leads to a line that was originally excited with a step function having energy flowing in both directions even though the current is zero all along the line.

Cecil simply sidesteps these little inconveniences by refusing to consider anything other than sinusoidal RF excitation and by refusing to consider any time based analysis. Such is not the path to understanding, deep or otherwise.

> you'll just come up with an even uglier generator to try to make it fit.

My generators are pretty simple. So far I have only used 3: Thevenin, Norton, and one with an interesting constant input power characteristic.

> oh, and by the way, your fancy 2 generator and 2 resistor 'constant
> power' source isn't what you think it is. go back to basic circuits

> equivalent.

You have confused a bit, models with implementation. As I said in the original: "Consider a generator constructed as below". I am not using an equivalent circuit, but a construction. Only when dealing with the actual construction is it valid to examine the internal energy flows. An "equivalent" circuit is equivalent for external behaviour but not necessarily for internal, so I avoid them when examining the internals.

but the equivalent points out that your statements about it sourcing
constant power is incorrect.

i have also pointed out that your statements about your 'step wave'
are obviously incorrect because you have applied assumptions that are

only valid in the sinusoidal steady state to a step function that can never be in steady state. neither can your pulses for that matter, so all the assumptions are worthless, you must do the complete analysis including the summations for the infinite fourier decomposition of your step or pulses to get the full picture... in a transient analysis. as was pointed out if you go VERY far into the future with a battery connected to an open circuit piece of coax there can be no currents and therefore no waves propagating in the line. its only in the detailed transient analysis that you haven't done where you will see the propagating steps going back and forth.

That's simply false. Using Fourier analysis, I reduce anything other
than a sinusoid to multiple sinusoidal RF excitations, perform the
sinusoidal analysis, and then use superposition to find the answer. I
also reject any example where Maxwell's equations do not work. Your
insistance that magical waves can somehow exist during DC steady-state
violates the known laws of physics. EM waves CANNOT exist during DC
steady-state because electrons are traveling at a constant velocity.
You can measure DC voltage with an AC voltmeter but that doesn't
change DC voltage to AC voltage.

In any region, the energy flowing in (i.e. power) to the region minus
the energy flowing out (i.e. power) is equal to the additional energy
per unit time (i.e. power) being stored in the region. While not
called the "conservation of power law" it is an obvious corollary
to "conservation of energy".

> The only question that needs to be
> answered is: In a system designed to eliminate reflections and

> in the source resistor. The answer is yes because there is nowhere
> else for it to go.

The obvious alternative is that the computed energy in the reflected
wave is sometimes just a figment. Or is something else happening with
the step function example?

Not to mention that in your 1/8 wavelength example (http://
www.w5dxp.com/nointfr.htm)
you do not explain where the energy is stored so that it can be
returned at a different time.

> There is no conservation of power principle and
> that includes instantaneous power. So it is irrelevant what/where

Such declarations do permit an easy out, despite not aligning with
reality.

> Now I understand that instantaneous power dictates some physical
> design considerations as in waveguides. But since instantaneous power
> does not fall under the conservation of energy principle, it is simply
> irrelevant to the present discussion. What happens over a complete
> cycle is what is relevant.

If that is the case, the whole concept of reflected energy seems
somewhat bogus. Over a whole cycle, the power delivered by the
generator is passed on towards the load. If that is all you want

to know, then there is no need at all for "reflected power".

> However, in any and every case, it is energy that is conserved,
> not power.

Yes. But see the related corollary above.

> How many joules are in that dt
> sliver of time when the instantaneous power is 100 watts? It's those
> joules that must be conserved, not the instantaneous power.

Still having problems with mapping the concepts from calculus to the
real world, I see.

> You didn't answer my previous question. If you measure 100 watts of
> instantaneous power at 100 places within an inch of each other, does
> that mean there is 10000 watts of instantaneous power in that one inch
> of wire? That is the only logical conclusion based on your argument
> and assertions.

No more than "If you measure 100 watts of *average* power at 100
places
within an inch of each other, does that mean there is 10000 watts of
average power in that one inch of wire?"

But it is a way of thinking that you like to use to distract
yourself from the really interesting results.

> Any argument based on the conservation of power is

So which is it? Is instantaneous energy flow a useful concept? Or is
it
not? You previously suggested an understanding of the value (when I
mentioned "real power folk"), but seem to continue to want to argue
its complete lack of usefulness.

And to stop besmirching Hecht, it seems most probable that his
comment was in the context of optics. After all, the book had that
title.

That does present a bit of a challenge to decipher.

Try using groups.google.com to read the message.

After opening the topic, scroll to the top and click "Options" which
should be found in the same header as the Topic. Click "Fixed font".

This significantly improves readability.

> principle, what happened to the energy in the two component voltage
> waves necessary for their existence before they cancel each other?

The fundamental question is: "did they have energy?"

Let us express this as a hypothesis:

Hypothesis 1: The component voltage waves have energy.

Then it should follow that we can trace this energy and discover
where it goes.

At least three examples have been proposed where the energy can
not be properly traced:

Example 1: Step function applied to a transmission line. After the
line settles, a forward and reflected voltage wave
continue on the line but no energy is being transferred.
Example 2: On a line with infinite VSWR no energy crosses a
voltage minimum or maximum.
Example 3: With the 1/8 wavelength line described in
http://www.w5dxp.com/nointfr.htm the energy can not be
properly accounted for on a moment by moment basis.

Only one counter-example was needed to disprove the hypothesis,
three have been found. There may be more.

Hypothesis is disproved.

No matter how many examples are found that support the hypothesis,
the hypothesis is still disproved.

Thanks Cecil:

Examples of you that I saw in recent weeks were about interferences generated by a single real generator and reflections, resulting, for example, in constructive/destructive interference responsible of changes in energy flow direction starting from the line point where those interferences occurs. In a nutshell: In post 127 I asked you for an example/experiment based in TWO real generators to assimilate it to more familiar double slit interference phenomenom (TWO coherent sources) rendering energy redistribution inside one dimensional TL space, two sources in tridimensional space gives maximuns and nulls on screen (redistribution). Well, I ask you for identical example in unidimensional space rendering a phenomenom similar as reflection (one wave) but with interference (two waves). Sorry I do not know how better translate my question to english words.
I not catched your answer because it does not match my question :>)

Thank you very much in advance. Miguel - LU6ETJ

I'm sorry, that is simply not true for power. The energy content of a
1us pulse containing one joule and the energy content of a one sec
pulse containing one joule are equal and that one joule is all that
must be conserved. The 1us pulse containing 1,000,000 watts can be
converted to a one second pulse containing 1 watt. Where did the other
999,999 watts go??? Energy has been conserved but the power changed
from 1,000,000 watts to 1 watt using exactly the same energy. Perhaps
this characteristic of power is what you are missing. Also, all the
energy can be conserved in reactance while power falls to absolute
zero. This often happens during a fraction of a cycle. That is what is
wrong with you trying to track instataneous power - it doesn't work
unless one standardizes to at least one cycle. Within each fraction of
a cycle, any principle of conservation of power will surely be
violated. If it appears that power is ever conserved, it is only by
accident. Such is the case with many megacycles/second where the
result of a fraction of a cycle will have a negligible effect on the
joules/sec.

> The obvious alternative is that the computed energy in the reflected
> wave is sometimes just a figment.

And God created the heavens and earth in six days and rested on the
seventh. I'm glad you are happy with your faith-based physics. In the
field of real-world physics, EM waves cannot exist without ExH energy.
The only way to win this argument is to prove to everyone that they
are not really detecting reflected waves containing energy when they
look at themselves in the mirror. Good luck on that one.

Question: How were the first three days measured before the creation
of the sun on the 4th day?

> Not to mention that in your 1/8 wavelength example (http://www.w5dxp.com/nointfr.htm)
> you do not explain where the energy is stored so that it can be
> returned at a different time.

Energy is stored in the transmission line and delivered as needed to
satisfy the conservaton of energy principle. Years ago, I showed how
energy can flow *into the source* (negative power) during a fractional
part of a cycle in a conjugately matched system.

> Such declarations do permit an easy out, despite not aligning with
> reality.

If you can take one joule per microsecond (1 megawatt) and conserve that one megawatt of power over a century, you can get rich selling it. Let us know when you get your patent on conservation of power. :-) Good Grief!

But, as you can grok from the subject of this thread, that is not all that is needed to know. The last gasp of the loser is that it didn't matter anyhow. Reflected energy has always mattered to optical physicists who know it obeys the laws of physics. Now it seems to matter to some hams. If it doesn't matter to you, why do you continue posting?

> And to stop besmirching Hecht, it seems most probable that his
> comment was in the context of optics. After all, the book had that
> title.

Hint: RF waves are covered in every physics book whose title is "Light". There is absolutely no difference, from a physics standpoint, between a coherent light wave and a coherent RF wave except for frequency. The both obey exactly the same laws of physics which you seem to concede for visible light but not for light at RF frequencies.

As far as I am concerned, if Maxwell's equations don't work on an example, it might as well be ignored. There is nothing during DC steady-state that allows Maxwell's equations to work because there are no EM waves during DC steady-state. Why don't you already know that?

I can take your approach and do you one better. Please prove that you exist. If you cannot prove that you exist, then nothing you say is of any consequence. See, I can do it also.

> Example 2: On a line with infinite VSWR no energy crosses a
> voltage minimum or maximum.

Completely false assumption. You are back to asserting that since the north-bound traffic equals the south-bound traffic on the Golden Gate Bridge that there is no traffic and no bridge maintenance is required. When are you going to give up on that irrational wet dream of yours? No *NET* energy crosses at a voltage zero or current zero point. That doesn't make the north-bound energy equal to zero and doesn't make the south-bound energy equal to zero. It just makes them equal. Just because there is no NET traffic flow on the Golden Gate Bridge doesn't mean there is zero traffic flow in both directions. Please stop clowning around with such absurb notions.

> Example 3: With the 1/8 wavelength line described in
> http://www.w5dxp.com/nointfr.htmthe energy can not be
> properly accounted for on a moment by moment basis.

There is no conservation of power principle. If you would track the RF joules and the conversion of RF joules to heat instead of the joules/second, everything would become clear to you. As it is, you are laboring under some serious misconceptions about the laws of physics. Power simply doesn't balance within a single cycle - because it doesn't have to - because there is no conservation of power principle.

People who don't learn from their mistakes are doomed to commit the same mistakes over and over. Keith, you seem to be all output and no input. Please enable your input channels for a change.

> constant power is incorrect.

You might like to actually test it. The two sources are always
delivering 100W.

With an open circuit load:
The current source is delivering 100 W to the parallel source
resistor.
The voltage source delivers nothing.
Total: 100W

With a shorted load:
The voltage source is delivering 100W to the series source resistor.
The current source delivers nothing.
Total: 100W

With a 50 ohm load:
The voltage source is delivering 50W.
The current source is delivering 50W.
Total: 100W
The load is receiving 50W.
Each generator resistor is dissipating 25W.

> i have also pointed out that your statements about your 'step wave'
> are obviously incorrect because you have applied assumptions that are
> only valid in the sinusoidal steady state to a step function that can
> never be in steady state.

I am not sure where you think there is an error. Perhaps you can
point them out in the following example:

Generator:
- 100V step in to an open circuit
- 50 ohm source impedance
Line:
- 50 ohm
- open circuit

Generator is commanded to produce a step.
This will produce 50 V and 1 A at the line input which will
propagate down the line.
The open end of the line has a reflection co-efficient of 1.0.
Just before the 50 V step reaches the end of the line, the
whole line will be at 50 V and 1 A will be flowing everywhere.
The 50 V step hits the end and is reflected, producing a 50 V

step (on top of the 50V already there) which propagates back
to the generator. In front of the 50 V step, the current is
still 1 A (which provides the charge necessary to produce
the reverse propagating 50 V step. Behind the step, the
current is 0.
When the reverse 50 V step (which is actually a step from
50V to 100V) reaches the generator, the source impedance
matches the line impedance so there is no further reflection.
The line state is now 100V and 0A all along its length.

The settling time was one round-trip.

The generator is still producing the step, so the forward
step voltage wave is still 'flowing' and being reflected so
there is still a reflected step voltage wave, each of 50 V.

Since the generator open circuit voltage is 100 V and the
line voltage is now 100 V, current is no longer flowing
from the generator to the line.

Does this agree with your understanding?

I have snipped the rest of your post since until the above
is agreed, there is no sense in proceeding further.

It is easy to put anyting on paper. Antenna gain advertisement was so bad
that many years ago the ARRL would not let anyone put gain numbers in their
advertisements.
Most things made by MFJ are not very well thought of in the US.

You need to expand your solution space. Some problems are so much
easier to solve in the time domain.

I can't even imagine doing some problems in the frequency domain.
Let's see: I turn on my flashlight maybe once per week, so the
fundamental is 1.6e-6 Hz, and say the risetime is 1 millisecond
-- my head hurts already -- that's about 600,000,000 harmonics to
be computed. No wonder you give up on some problems so readily.

> I also reject any example where Maxwell's equations do not work. Your
> insistance that magical waves can somehow exist during DC steady-state

It is not my insistence. It follows from the math.

Besides if you convert it to the frequency domain you should
be happy that they exist since they then align with your
understandings.

> EM waves CANNOT exist during DC
> steady-state because electrons are traveling at a constant velocity.

Are you sure you meant this? The electron velocity changes? Or did
you mean the wave velocity? Nope. That does not work either.

> You can measure DC voltage with an AC voltmeter but that doesn't
> change DC voltage to AC voltage.

And for especial fun... Why are you sure DC is so special?
v(t)=A cos(wt)
describes a sinusoid. It has the parameter w to specifiy the
frequency. Set it to 0, and voila: DC. It falls right out
of the same definition as is used for a sinusoid. It is a
sinusoid.

Sorry, I ommited aknowledge to you I understoond your example and what you mean with:

"What happens to Vfor1(rho) = 50v(0.7143) = 35.7v? "
"What happens to Pfor1(rho^2) = 50w(0.51) = 25.5w? "

(Last represent the cancellating (interference?) term of transmitted power (1.Rho^2) towards generator from the reflected power from the load to render VRef1=0 (doing the accounts with phasorial V-I math, though I suppose will give similar results employing the eq-1 of your World Radio article, but I am not sure if I'm catching it very well yet. Have you P1, P2, P3 and P4, for your 100 W example, to clear it?)

Perhaps some of your difficulty is revealed in your phraseology. A
pulse does not 'contain' power. It can deliver energy at some rate.
If the pulse is rectangular, the rate will be constant for the
duration of the pulse. With some other profile, the rate will
vary over the duration of the pulse.

Perhaps a simple analogy would help. Near my house is a 50 m water
tower with a bunch of pipes connected to the bottom. The rate at
which water is added to the tower is always equal to the sum
of the rates flowing in on all the pipes (assume positive flow
raises the level in the tank, while negative flow reduces it).

Rephrased, for greater certainty: At any instant in time, the
rate at which water is being added to the tower is always equal
to the sum of the rates flowing in on all the pipes.

At any instant in time, all the water (and flows) can be
accounted for.

Same for energy (and energy flow).

Did I miss something? Was it not you who said "What happens over a
complete cycle is what is relevant."?

> seem to concede for visible light but not for light at RF frequencies.

Several differences:
- Transmission lines work down to DC
- At lower RF, it is possible to independantly measure voltage and
current

This allows a better understanding of the behaviour, not constrained
by the capabilities of the mearsuring instruments.

I always thought that Maxwell's equations were more complete than that
and worked all the way down to DC. Two of them do not even include
time
and nothing says that a derivative with respect to time can't be 0.

> I can take your approach and do you one better. Please prove that you

I suppose, but then you have to give up on P(t)=V(t)*I(t), generally
considered to be a rather fundamental equation.

There is no mention of power above; simply energy.

Are you saying that conservation of energy only applies some of
the time?

In your example, the RF energy does seem to disappear and re-appear,
when tracked on a moment by moment basis.

Unfortunately for your arguments, math models do not dictate reality.
If the math model doesn't match reality, it is invalid. Your math
models obviously do not match reality.

> Are you sure you meant this? The electron velocity changes? Or did
> you mean the wave velocity? Nope. That does not work either.

Yes, acceleration and deceleration of electrons (in the conductor) is
required for EM waves to even exist. That's an obvious change in
electron velocity. Is that another fact of physics that shoots your
theory down? I repeat: EM waves are impossible during DC steady-state.

Nope, I believe you are only a figment of my imagination. Please prove
that you actually exist.

> I suppose, but then you have to give up on P(t)=V(t)*I(t), generally
> considered to be a rather fundamental equation.

I have absolutely no problem with giving up on the conservation of
power principle in which no rational technical person can possibly
believe.

> Are you saying that conservation of energy only applies some of
> the time?

No, I am saying that if you cannot balance the energy equation at all
times, you have made a mistake. You are not tracking joules. You are
attempting to track watts which can appear and disappear at any time.
The only condition where watts can be tracked is over an integer
multiple of complete cycles. That's why watts can be tracked when the
frequency is in the MHz. Trying to track instantaneous watts within a
fraction of a cycle is a moronic attempt at power superposition, a no-
no that we all learned in EE101.

> In your example, the RF energy does seem to disappear and re-appear,
> when tracked on a moment by moment basis.

No, the power can disappear and re-appear but the energy cannot. You
have not even come close to tracking the energy.

> Well, it would help if you could actually find and articulate a flaw
> inhttp://sites.google.com/site/keithdysart/radio6.

The flaw is your belief in a conservation of power principle that
doesn't exist. Instantaneous power is not required to obey any
conservation principle. What you are doing on that web page is
attempting to superpose powers apparently without a clue.

Superposition of power is a no-no. The power density equation allows
us to accomplish the addition of *average* powers taking interference
into effect. I know of no such mathematical equations for
instantaneous power and your instantaneous power superposition
technique is obviously invalid.

of course they do constant electric field and constant magnetic fields
work just fine and go out to infinity in the dc steady state case.
this of course means there can be no moving electrons, therefor no
current, no d/dt terms, etc... which means no waves.

very fundamental, and very restricted. only good for one point in
space at one time, and for one pair of voltage and current
measurements... can not be applied to separate waves that are
superimposed, only to the final total voltage and current at the
measurement point at that instant.

There again, a non-sequitor non-answer.

Do you reject P(t)=V(t)*I(t) ?

I agree completely. And my analysis does successfully track all the
energy at all times.

And after averaging, it even agrees with your analysis.

Methinks that you are perturbed that it demonstrates that your
analysis
does not track all the energy all the time, but only succeeds with
averages.

True, but others reject it completely.

The teaser is amusing, but hardly relevant. In my example, all of
the energy is tracked. Or, I invite you to point out that which was
overlooked. Cecil has not found any and would rather prattle on about
the difference between energy and power than actually understand.

Time, of course. I agree, though, it is not as clear as it could
have been. It helps a bit if you look at Cecil’s schematic.

Still, it is complicated and will probably take some effort to
understand.

It would probably be better to start with the step wave example
offered previously in another post and copied below for

convenience:

<example>
I am not sure where you think there is an error. Perhaps you can
point them out in the following example:
Generator:
- 100V step in to an open circuit
- 50 ohm source impedance
Line:
- 50 ohm
- open circuit
Generator is commanded to produce a step.
This will produce 50 V and 1 A at the line input which will
propagate down the line.
The open end of the line has a reflection co-efficient of 1.0.
Just before the 50 V step reaches the end of the line, the
whole line will be at 50 V and 1 A will be flowing everywhere.
The 50 V step hits the end and is reflected, producing a 50 V
step (on top of the 50V already there) which propagates back
to the generator. In front of the 50 V step, the current is
still 1 A (which provides the charge necessary to produce
the reverse propagating 50 V step. Behind the step, the
current is 0.
When the reverse 50 V step (which is actually a step from
50V to 100V) reaches the generator, the source impedance
matches the line impedance so there is no further reflection.
The line state is now 100V and 0A all along its length.
The settling time was one round-trip.
The generator is still producing the step, so the forward
step voltage wave is still 'flowing' and being reflected so
there is still a reflected step voltage wave, each of 50 V.
Since the generator open circuit voltage is 100 V and the
line voltage is now 100 V, current is no longer flowing
from the generator to the line.
Does this agree with your understanding?
</example>

this is different than what you claimed before. on june 17th you
claimed:
If(t) = 50/50 = 1a
Ir(t) = 50/50 = 1a
now you sy current is no longer flowing.

i will object to you saying the voltage 'wave' is still flowing. The line is at a constant 100v, there is no current, there can be no em wave without current AND voltage, therefore voltage can not be flowing.

On Jun 28, 5:27 pm, Keith Dysart <keith.dys...@gmail.com> wrote:
> And yet, you have not located any errors in the math or the models.

Superposition of power *IS* an error! You add and subtract powers willy-nilly as if that mathematical step were valid which it is not. Two coherent 50w waves do not add up to a 100w wave, even using average powers, except for the special case of zero interference where the waves are 90 degrees out of phase with each other.

In order to use power as an energy tracking tool, we must be very careful to ensure that there is a one-to-one correspondence between energy and power, i.e. every joule passing a point in one second must result in one watt of power (no VARs allowed). If that one-to-one correspondence doesn't exist, no valid conclusion can be drawn from tracking the power and any valid conclusion must be based on tracking the energy which is no small task. The key is that there is no such thing as imaginary energy. All energy is real. Some "power" is not real.

A one-to-one correspondence does not exist in a standing wave. Therefore, tracking power as if it were equivalent to energy in standing waves is invalid. You have made that error for years.

One-to-one correspondence also does not exist over a fraction of a wave. Therefore, instantaneous power is irrevelent in tracking the energy. That's your latest error which is the same conceptual error as before. In general, average power in the traveling waves over at least one complete cycle (or over many cycles) has a one-to-one correspondence to the average energy in the traveling waves. But that one-to-one correspondence is more often than not violated within a fraction of each cycle.

Here's a quote from "Optics", by Hecht, concerning power density (irradiance).

"If however, the 'T' is now divided out, a highly practical quantity results, one that corresponds to the average energy per unit area per unit time, namely 'I'." - where 'I' is the irradiance (*AVERAGE* power density).

If I calculate the Z0 of a 1/4WL transformer, I get two roots when I take the square root of R1*R2. One of the roots is negative. If I ask you to prove something is in error with the math that yielded a negative Z0, could you find the math error? If not, does it follow that you can find the transmission line with the negative characteristic impedance existing in reality?

That's your argument in a nutshell. There may (or may not) be an error in your math but it doesn't matter either way. The conclusions that you reach from your math do not match reality so your math is a moot point, i.e. there is no one-to-one correspondence between your math and the real world.

If you have forgotten the importance of the one-to-one correspondence concept in mathematics, now would be a good time to review that concept. Without a one-to-one correspondence to reality, math is just fantasy existing only in your mind.

I certainly reject as a moronic method for attempting to track
instantaneous energy.

> I agree completely. And my analysis does successfully track all the
> energy at all times.

That is obviously false. You have tracked the *power* after assuming a
one-to-one correspondence between power (watts) and energy (joules).
Your assumption is most likely false. You usually cannot use
instantaneous watts to track joules within a fraction of a cycle. If
the voltage and current are out of phase, some of the joules are
occupied as reactive power, and not available as watts of real power.
Why do you think the power companies spend so much money trying to
balance the power factor?

> Methinks that you are perturbed that it demonstrates that your
> analysis does not track all the energy all the time, but only
> succeeds with averages.

What bothers me is that, "Figures don't lie, but liers figure." :-) I
have made no assertion or effort to track instantaneous energy. I
would have to review a lot of physics to even remember how. What I do
know is that you have been tracking power, not energy, and therefore
any conclusion that you reach is probably invalid. You first must
prove a one-to-one correspondence at all delta-t sections between the
joules at that point and the watts at that point. We know that
integrating over a complete second will make the joules equal to the
watts for a traveling wave (but not for a standing wave). Now you must
integrate over every partial cycle to prove that there are the exact
number of joules in that delta-t of time to support the exact number
of watts in that delta-t of time. I remember being warned by my
professors more than half a century ago that it was a "fool's
errand".

I have listed a number of the laws of physics that you are violating. Of course, energy and power are different. Consider an ideal LC oscillator at the instant of time when the voltage on the capacitor is maximum and the current is zero. The energy is certainly not zero and can be calculated knowing the voltage and capacitance (assume 1000 volts and 1uf). Yet the instantaneous power is zero because the instantaneous current is zero.

energy = (V^2*C)/2 = 0.5 joule

power = V(t)*I(t) = 0

Please prove a one-to-one correspondence between energy and power. How can you possibly say that you are tracking all the energy when the power equals zero and the energy does not? Good grief!

> I am not sure where you think there is an error.

Again, you need to cut off your output and enable your inputs. There are no waves during DC steady-state. Therefore, there are no forward waves and no reflected waves. Therefore, you basic assumptions are invalid. For waves to exist there must be acceleration and deceleration of carrier electrons and such does not exist during DC steady-state. Why don't you know that?

Why don't you know that oscillating current goes into the displacement
current. In EM no reflections.

You should decide: EM or electrons. The mixture is fun.

That's an interesting idea to which I don't know the answer. Let me
rephrase the question:

Although it is known that electrons cannot flow through the dielectric
of an ideal capacitor, how about photons? Can RF photons flow directly
through the dielectric layer of a capacitor? If they can, it would
explain a lot of things.

Dear friends, I follow with interest your interesting digressions,
however in various different posts about differents matters, I notice
discussion arises about what is "real" and what is not. IMO that
contributes to the solution goes away from us (I remember making this
comment in a previous post). In this sense respecto to energy I would
like to quote a great physics:

"...there is a certain quantity, which we call energy, that does not
change in the manifold changes which nature undergoes. That is a most
abstract idea, because it is a mathematical principle; it says that
there is a numerical quantity which does not change when something
happens. It is not a description of a mechanism, or anything concrete;
it is just a strange fact that we can calculate some number and when
we finish watching nature go through her tricks and calculate the
number again, it is the same."

"It is important to realize that in physics today, we have no
knowledge of what
energy is. We do not have a picture that energy comes in little blobs
of a definite
amount. It is not that way. However, there are formulas for
calculating some
numerical quantity, and when we add it all together it gives "28"'—
always the
same number. It is an abstract thing in that it does not tell us the
mechanism or
the reasons for the various formulas."

I learnt displacement current inside a condenser it was = eo* d(phi E)/
dt no EM radiation inside the condenser to made that current possible,
in any case EM radiation in physical condenser will come out from
condenser to the rest of the universe :>).
I also learnt photons was necessary to explain certain energy
interchange phenomena such as fotoelectric effect or subatomic
particle interactions, wave-particle duality for me means "duality",
not "wave kaput" :>) to account for EM wave well explainable
phenomenom.
As it was taught to me (I am not physicist), quantum nature of a 80 m
wavelenght energy it is useless for calculations and invisible to our
instrument resolution because its immensely large quantic number. Is
it wrong?

rephrase the question:

>Although it is known that electrons cannot flow through the dielectric
of an ideal capacitor, how about photons? Can RF photons flow directly
through the dielectric layer of a capacitor? If they can, it would
explain a lot of things.

Photons are in the real light. The natural light is not coherent. It is
emitted in the portions (packets).
Radio waves are emitted continously. Radar waves are in the portions.

Radio waves and the light photons flow directly through the dielectric layer
of a capacitor.

The difference between EM and electrons is in compressibility.
Electrons are compressed in the ends of the open circuit (condenser and
antenna). There the voltage is doubled (at least). Alternate electric field
is created. It is radio wave. The longitudinal electric wave.

In Heaviside EM (hydraulic analogy) incompressible current (real +
displacement) create the magnetic whirl.
The oscillating magnetic whirl is the transverse wave.

Electrons are simple. Heaviside did not understand Maxwell and made a
complete mess.

Then shouldn't we all expect a condensor to be as good a radiator of
EM waves as a dipole?

Any energy that might raise the temperature is accounted for in the
source and load resistors, so I still suggest that no energy sources
or sinks have been missed.

I think I detect a bit of a problem originating with definitions.

Start by considering that old stalwart from the text books: the
infinite transmission line. For convenience, the characteristic
impedance is 50 ohms and at the left end is attached a generator
with a 50 ohm source impedance. The transmission line extends
to the right forever, and this time the generator produces a
sinusoid.

Turn on the generator and it starts to produce a sinusoidal wave.
For greater certainty in the description let us say that the
function which describes the wave is:
V(t) = 100 cos(wt)
where w is the ascii excuse for omega, the angular frequency.

Because the line is accepting this signal and transporting it
away from the generator, the voltage distribution on the line
is also a sinusoid, but spatially distributed along the line.

We can visualise this spatially distributed sine wave as
moving along the line and thus we have the term travelling wave.
If we run fast enough along the line we can get to a point
where the signal has not yet arrived and the line is at 0V,
and if we wait, the sine wave will eventually arrive and
we will observe the same sinusoidal spatially distributed
voltage pattern moving along the line.

We can run the experiment with the generator producing other
functions of time and we would observe the same function
spatially distributed along the line and moving.

A generator producing a square wave will produce a square
wave voltage distribution moving along the line.

A generator producing pulses will result in pulses moving
along the line.

A voice signal will result in a complicated voltage pattern
moving along the line.

This holds for any wave, V(t), produced by the generator.

But most lines are not infinite. What happens when the line
is terminated? Most texts will explain that if a section

of line is terminated in its characteristic impedance, that section will behave as if it was connected to a line that continued forever. That is, the observations on that section will be no different than if the line went on and on and on.

Thus in that section we would observe the moving sine, square, pulse, or whatever wave, but, we can no longer run far down the line to find a place where the wave has not yet arrived, since the line has been truncated.

Now what happens if our section of line is open-circuited? The wave reflection model allows us to compute that the reflection coefficient (rc) will be 1. This means that if a forward travelling voltage wave, Vf(t), encounters the open circuit, it will be reflected as a reverse wave, Vr(t).

Mathematically
Vr(t) = rc * Vf(t)

Going back to our waveforms, this is most readily visualised with pulses where the repetition rate is low enough that only one pulse is on the line at a time. The pulse can be seen to travel down the line, hit the end and travel in the reverse direction back to the generator. What happens when the pulse gets back to the generator? Well the generator was specified to have a source impedance that was the same as the line characteristic impedance, so the behaviour on the section of line will be exactly the same as if the line continued forever. There is no reflection, and we can forget about the pulse.

The wave reflection model also tells us that the voltage at any point on the line will be
V(t) = Vf(t) + Vr(t)
where Vf(t) is the voltage from the forward wave at that point on the line and Vr(t) is the voltage from the reverse wave at that point on the line.

For pulses, where there is only one pulse on the line at a time, this is easy to visualise, but for continuous signals, the voltage distribution on the line is now the sum of the forward and reverse travelling waves and for the most part, the forward and reverse travelling waves are no longer easily visible. For example, with a sine wave, the resulting voltage distribution on the line is the time varying, so called, standing wave.

It is important to note that even though the original travelling waves are no longer visible in the spatial

distribution of the voltage on the line, the travelling wave continues to be provided by the generator, it travels to the end of the line where it is reflected and this reverse wave travels back to the generator where it behaves as if the line continued forever because the line is terminated by its characteristic impedance.

Recall that all of this holds for any Vf(t) produced by the generator. So what happens with that original sticking point, the step function?

Consider the infinite line again. The step is moving along the line. If we run far enough ahead, we can watch the step pass, but behind the step the voltage is constant. This makes it hard to visualise as a moving wave because there are no peaks and valleys to observe, but it is still moving. If in doubt, just run further down the line to observe the step pass again.

Now if we terminate the line, we can no longer run on ahead to find the step, but the wave is still moving; we just can’t see it because of the constant nature of the wave after the step.

With the open circuited line, the step function is reflected and travels as a reverse wave back to the generator. Once the step reaches the generator, just as happens for any other V(t) wave, the wave continues to move; it just is not visible. And the voltage at any point on the line can be correctly computed from
V(t) = Vf(t) + Vr(t)

Another way to think of this is to produce the step wave in a different manner. Start with a pulse wave. Then increase the pulse width until it approaches the pulse period. The variation in voltage can still be observed on the line. Then slowly increase the width until it is equal to the period. There is now no longer any variation in the wave to be observed, but the wave is still moving just as it was when the width was infinitesimally shorter than the period.

Another view is to start with a square wave, then increase the period until it is much longer than the duration of the experiment. Over the duration of the experiment, no change in voltage will be observed, but it is a square wave. One could perform a Fourier transform on the square wave, treat all the constituent sine waves as travelling

waves, work out the reflections for each, and sum them back. Exactly the same results will be obtained as will be for treating the step as a moving wave, even though there are no peaks and valleys to aid the visualisation.

So I hope that I have persuaded you that it is completely valid to view a step function as a wave that continues to move (though it is hard to see) even after the step has passed.

If not, re-read the above to locate the flaw in my argument.

If you have been convinced, then we can get back to
If(t) = 50/50 = 1a
Ir(t) = 50/50 = 1a

Consider a generator, 50 ohms, that produces a 50 V step in to 50 ohms. For this
Vf(t) = 50V
The line has a 50 ohm impedance, so
If(t) = 50/50 = 1A

This is the voltage and current that would be observed on the infinite or terminated line after the step passes.

With the open circuit line, where the reflection coefficient is 1, the voltage will be reflected so that
Vr(t) = 50V
after the reverse step passes and
Ir(t) = 50/50 = 1A

Recalling that at any point on the line
V(t) = Vf(t) + Vr(t)
and
I(t) = If(t) – Ir(t)

we have, after the reverse step has returned to the generator, everywhere on the line:
V(t) = 50 + 50 = 100V
I(t) = 1 – 1 = 0A

This is exactly as expected for a generator with an open circuit voltage of 100V and an open circuit line that has no current flowing.

So the wave reflection model, with continuously forward and reverse waves, accurately describes the resulting observations on the line, even for

a step wave.

You have really latched on to that haven't you. I remember the good
ol'
days when you were superposing powers and the very same people with
whom you are arguing today were trying to convince you that
superposing
power was an invalid operation.

Now you have bought in to the rule and apply it even where it does
not apply.

Just because a sum is being computed does not mean that superposition
is at work.

When you add up the energies to validate that energy is not created
or destroyed, you are not superposing energy.

When I add up the energy flows for the same purpose, that does not
mean that superposition is at work.

From a basic calculus, if the energy balances, so must the energy
flow:

f(t), g(t), etc. are functions that describes the energy in
individual entities of a system with respect to time. Then

f(t) + g(t) + h(t) = k

is the expression that says the sum of all the energies must be
a constant, for energy is neither created nor destroyed.

From basic calculus

d(f(t) + g(t) + h(t))/dt = d(k)/dt
d(f(t) + g(t) + h(t))/dt = 0
d(f(t))/dt + d(g(t))/dt + d(h(t))/dt = 0

d(f(t))/dt is the derivitive with respect to time of the energy
(i.e. energy flow, or power) for the entity.

So it is completely valid to sum these energy flows to
track the energy within the system; as my example does.

> You add and subtract powers

True. You must always use the actual energy flows in the entity and
not the powers that are not real.

> In order to use power as an energy tracking tool, we must be very
> careful to ensure that there is a one-to-one correspondence between

> thing as imaginary energy. All energy is real. Some "power" is not
> real.

Agreed. Especially the power in the waves that are being superposed.
That is why you need a fudge factor when you sum your partial powers
from your waves. I carefully do not sum partial powers from
superposed waves.

> A one-to-one correspondence does not exist in a standing wave.

Of course it does. Energy must always balance; not just at the end
of the cycle.

> fraction of each cycle.

Now you are allowing us to create and destroy energy as long as it
balances at the end of the cycle? Are you sure you want to do this?
It does not align with the well understood principle of conservation
of energy.

If I follow that rule, I just make the cycle long enough, say, my lifetime, and I am golden.

But I do not hold out any hope for this.

> Here's a quote from "Optics", by Hecht, concerning power density

There you go again, assuming that the 'practical' challenges of optics also apply to transmission lines. On a transmission line, we can measure the voltage and the current. We do not suffer from the same constraints as optics.

Use the tools that are available for transmission lines. Don't tie two hands behind your back just because those tools do not work in the optical domain.

> instantaneous watts to track joules within a fraction of a cycle.

Of course you can. It is just like water flowing from multiple pipes
in to a tank. The sum of the instantaneous flows is exactly equal
to the rate at which the volume of water is increasing in the tank.

Not hard at all.

> If
> the voltage and current are out of phase, some of the joules are
> occupied as reactive power, and not available as watts of real power.

Mostly true. But this is accurately accounted for by using the
instantaneous voltage and current and not the RMS. This is an
important difference expressed in

P(t) = V(t) * I(t)

and why I do not use

Pavg = Vrms * Irms

which has all the problems you mention.

> Why do you think the power companies spend so much money trying to
> balance the power factor?

Not for this reason. The energy meter at my house accurately
measures the power (using P(t) = V(t) * I(t)) and integrates
so that they bill me for the energy I have used. And so they do.

Poor power factor does not affect this, but increases the losses experienced by the power company when delivering the energy to me. They want the customer to pay for these losses so they monitor VAR.

Indeed. Power and energy are related in that power is the derivitive
with
respect to time of energy. They are very closely related. See my
other
post for the derivation.

> Please prove a one-to-one correspondence between energy and power. How
> can you possibly say that you are tracking all the energy when the

'cause that is how calculus works!? If one tracks all the flows, then
one knows where the energy is because it can only move by flowing.
Think water pipes and tanks for an analogy.

You, yourself, explained once how you would use the Fourier transform to analyze such an example. After you have transformed the signal to the frequency domain, there are enough sinusoidal waves to keep anyone happy.

Or are you saying that a step function does not have a Fourier transform?

The antenna is electrically a half wave on 10M to 40M, the electrical
length of an element is not directly related to it's physical length.
That is how they make a "halfwave" in a stick shorter than a physical
quarter wave.

The line "full size halfwave on 2/6 meters" indicates that on those two
bands the antenna is not loaded, but actually physically a halfwave
antenna. The manual indicates that as initially built to dimension,
before adjustment, the antenna is centered on 51 MHz on 6M, and 146 MHz
on 2M, so my assumption s it is acutally a halfwave on those two freqs.

> in any case EM radiation in physical condenser will come out from
> condenser to the rest of the universe :>).

It depends on your definition of "radiation". In an ideal transmission line, energy is not lost to radiation but photons (EM fields and waves) necessarily exist all up and down the line. In an ideal coaxial transmission line, the photons (EM fields and waves) are confined to the dielectric. Electrons cannot travel at the speed of light. EM waves travel at the speed of light. Therefore EM waves are photons. Given the physical nature of a capacitor, refraction would be the primary mechanism for losing energy to radiation and there's probably very, very little refraction in the capacitor dielectric. If electrons are being acelerated and decelerated in the capacitor, photons will be emitted. It seems obvious now that when electrons are decelerated on one capacitor plate, photons are emitted that propogate across the capacitor dielectric and are absorbed by electrons on the opposite plate. When the concept of displacement current was invented, nobody knew that RF fields were actually made up of particles (photons) but now we do know. Displacement current seems only to be EM radiation from one capacitor plate to the other.

> instrument resolution because its immensely large quantic number. Is
> it wrong?

The quantized nature of a single RF photon is no longer open to argument and the energy in that single photon can be calculated, (h*f), where h is Planck's constant, 6.626 x 10^-34 J*s. Whether there are any instruments sensitive enough to detect a single 80m photon is a moot point that does not change the nature of RF fields and waves. What is important is that it is impossible to radiate a signal level less than (h*f). If anyone asserts that RF fields and waves can violate the laws of physics regarding photons, that person is wrong and delusional. (Light left over from the time when the universe became transparent is today red-shifted down to RF microwave frequencies and called background radiation.)

Laser light can usually be considered to be coherent light as are
waves generated by an RF transmitter. But of course, nothing is
perfect.

> Radio waves and the light photons flow directly through the dielectric layer
> of a capacitor.

Energy flow, just not as "current".

> Electrons are compressed in the ends of the open circuit (condenser and

"Compressed" may be overstating the phenomenon. Have you ever
calculated exactly how far an electron moves at 10 MHz?

> Electrons are simple.

Yes, too simple to move at the speed of light.

2826. Using a 18" Dish for Radio Astronomy Demonstrations--Need Simple Power Supply

Newsgroup: rec.radio.amateur.antenna

Somewhere I came across a setup for a simple "itty bitty" radio telescope a number of years ago. Its purpose is educational. Basically, it consists of a discarded 18" dish, power supply, and a satellite signal finder. I happen to have a Channel Master 1004ifd finder, but it gets its power from the LNB, which apparently gets it from a satellite rcvr. I have no rcvr. Is there some simple inexpensive 12v dc power supply (battery pack) that I could use? I would guess that it would need a connector of some sort to hook to the LNB.

And I remember the good ol' days when you were still messing your diapers. Do you still do that? I probably did try to superpose power back when I was young and foolish but I learned the error of my ways and corrected it.

> When I add up the energy flows for the same purpose, that does not
> mean that superposition is at work.

But you are NOT adding up the energy flows - you are adding up the power. That's superposition of power and is a no-no. Power does not obey any conservation of power principle. The instantaneous maximum charge on a capacitor contains any amount of energy while power equals zero. What is it about that concept that you don't understand?

> True. You must always use the actual energy flows in the entity and
> not the powers that are not real.

What happens when energy = 1 joule, and de/dt = 0 watts. This happens all the time during an RF cycle so you are not using actual energy flows. You are using power which goes to zero even when maximum energy is still present. There is obviously NOT a one-to-one correspondence between power and energy.

YOU CANNOT USE WATTS TO TRACK ENERGY UNLESS THERE IS A ONE-TO-ONE CORRESPONDENCE BETWEEN WATTS AND JOULES.

> Also true. And as is done in my example.

Actually false, as I have proved above. Please plot the joules, not the watts.

> Please provide an example of such an error, preferably from one
> of my expositions.

At a current node in a standing wave, you claim there is zero power which is true. You claim that since there is zero power, there is also zero energy which is absolutely false since that is a voltage maximum point and you will fry yourself if you grab it. The energy in the voltage maximum is unrelated to the power being zero - just one more proof that energy does not correspond to power. At the zero power points, there is a maximum of energy in one of the fields which you

are ignoring.

> Of course it does. Energy must always balance; not just at the end
> of the cycle.

Energy must balance but power doesn't have to balance and usually does not balance. Power only balances for special cases. You are using power in the general case as an example so anything you say is invalid.

> Now you are allowing us to create and destroy energy as long as it
> balances at the end of the cycle?

No, energy cannot be created or destroyed. But power is created and destroyed all the time because there is no conservation of power principle. Your glaring error is that you are using power as if it were energy and it is not. I have given numerous examples. In an LC oscillator, when all of the non-destructable energy is stored in the capacitor, there is ZERO power, i.e. power has been destroyed. Why do you refuse to discuss that fact of physics? 90 degrees later in the cycle, power has been created.

Every time one of your instantaneous power curves crosses the zero axis, power has been destroyed. Every time one of your instantaneous power curves reaches a peak, power has been created.

> We do not suffer from the same constraints as optics.

You suffer from the delusion that power obeys the same laws of physics that energy does. You willy-nilly interchange power and energy. Until you admit the error of your ways, there is little that can be done to alleviate your ignorance.

Your example has the step function disappearing during steady-state.
DC steady-state has no Fourier transform since omega equals zero. A
Fourier analysis requires a recurring function of the sum of sinusoids
involving integer multiples of omega*time. Your single step does not
recur so your conclusions are invalid.

WEll, lucky me. A small amount of Googling got me to
<http://www.aoc.nrao.edu/epo/teachers/ittybitty/procedure.html>
I'm not sure our local The Shack has a choke. I may have one. My LNB is
different than the one in the pic. It's a Eagle Aspen DTV32+. I'm sure I
have a battery clip and 8 battery holder. This might do it. I didn't
notice the Rx connector on my CM, but that is where the power goes. I
may be set.

Check the a0 coefficient in the Fourier transform. This represents
the DC component of the signal. It is perfectly valid for it to be
the only non-zero coefficient.

Without this, how would you deal with a signal such as
V(t) = 10 + 2 cos(3t)

Alternatively, one can use the standard trick for dealing with
non-repetitive waveforms: choose an arbitrary period. 24 hours
would probably be suitable for these examples and transform from
there. Still, you will have zero frequency component to deal
with, but there will be some at higher frequencies (if you
choose your function to make it so).

Ummm. Energy flow is power. Joules/s!

If it helps, any place I have written 'power', please replace with
'energy flow'.

> That's superposition of power and is a no-no. Power does not
> obey any conservation of power principle.

Try the multiple pipe, water container, water flow example to
understand how flows must also be conserved if matter (or
energy) is not to be created or destroyed.

> The instantaneous maximum
> charge on a capacitor contains any amount of energy while power equals

Excellent concept. There is no conflict with conserving flows, or
energy
for that matter.

Yes, indeed. That is a fundamental possibility and occurs on
transmission lines with infinite VSWR.

> There is obviously NOT a one-to-one correspondence
> between power and energy.

Correct. Power is the time derivitive of energy. They are related
but definitely not one-to-one.

> YOU CANNOT USE WATTS TO TRACK ENERGY UNLESS THERE IS A ONE-TO-ONE
> CORRESPONDENCE BETWEEN WATTS AND JOULES.

This is quite incorrect. Energy flows must balance, otherwise energy
is being created or destroyed to sustain a difference in flow.

> > Also true. And as is done in my example.
>
> Actually false, as I have proved above. Please plot the joules, not
> the watts.

If it makes you happier, since it is a discrete simulation, you can
simply substitute joules per degree wherever there is a curve labeled
Watts. You need to scale, of course, between degrees and seconds, but
the shape and sums will be identical.

> > Please provide an example of such an error, preferably from one
> > of my expositions.
>
> At a current node in a standing wave, you claim there is zero power
> which is true.

Excellent. I am glad you have come to accept that.

> You claim that since there is zero power, there is also
> zero energy

I have never claimed that. In fact, the minima and maxima are
where the energy peaks will be found. I have claimed there is
no energy flow across (i.e. power) these points.

> which is absolutely false since that is a voltage maximum
> point and you will fry yourself if you grab it. The energy in the
> voltage maximum is unrelated to the power being zero

Not quite. It follows from the functions for each. Since power is
the derivitive of energy, it should come as no surprise that
maximum energy occurs at the point of minimum power. In basic
calculus looking for the zero in the derivitive is how you
locate the maximum value of the curve.

Unfortunately wrong. Energy flows must balance as well. Otherwise,
energy is coming from nowhere to sustain the flow.

Yes, indeed. At that instant, zero energy is flowing from the inductor
to the capacitor. But very soon, energy will be flowing from the
capacitor to the inductor. The balance is that the energy flowing
out of the capacitor is always and exactly equal to the energy flowing
in to the inductor. That is the energy flow balance. The only way for
this not to be true is for energy to be created or destroyed.

> Why do
> you refuse to discuss that fact of physics? 90 degrees later in the
> cycle, power has been created.

One way of thinking about it, I suppose. But not too useful.

Instead, think that at every instant, the energy flow between the
entities in the experiment must balance.

> Every time one of your instantaneous power curves crosses the zero
> axis, power has been destroyed. Every time one of your instantaneous
> power curves reaches a peak, power has been created.

I think you may be confused because you are only looking at the
flow in and out of a single entity. This is clearly not conserved.
Nor for that matter is the energy within that entity. It is the
total energy within the system that is conserved, just as it is
the total of the flows of energy between the entities within the
system that must be conserved.

Put more strictly: The sum of all the energy flows in to all of
the entities within the system must equal the energy flow in to
the system.

An intriguing accusation, but you do need to provide a concrete
example of where my analysis has gone wrong.

Yes.

We experience 80M activity every day irrespective of it being
Newtonian or Quantum. All it reveals is that something with a very,
very, very low energy is still quite measurable.

However, you "can" deliberately choose the wrong instrument to measure
the energy. That instrument reveals more about the choice-maker than
the energy.

For instance, a 1KW 80M energy source presents a near 0 degree
absolute temperature. A fever thermometer is not going to register
that energy.

> Richard Clark, KB7QHC

Dear Richard:

What I said is what my physics book says, I swear there no creation of
mine... :>) (I have not any authority on this matter).
I was thinking in quantic number describing the energy of a typical
100 W 80 m oscillator devolped in one second, representing a quantic
number n = 4.3 * 10^28; we know our quanta represents the minimun
possible energy of a 80 m radiation AND the minimun "delta" Energy
possible for a given oscillator, energy difference between (among?)
one quanta an two quanta of 80 m radiation is 2.3 * 10^ -27 J, that
difference (my physic book say) it is unmeasurable experimentally
(this energy leap (skip?, hop?) it is in the order of 10^-8 smaller
that green light leap (in reality my book -Resnick Halliday- give a
moving dust particle example with quantic number very much lower than
my 80 m example yet => n = 3 * 10^14, they said "we can not
distiguish energy difference among n = 3 * 10^14 and n = [3 * 10^14]
+1")
What it is the ohysical sense of working with magnitudes we can not
measure? Nobody (as we know) use (or need) quantum mechanics to deal

with (or explain) locomotive movement :>)

Cecil said "electrons can not travel at light speed, photon yes therefore EM waves are photons", well... EM CAN travel at light speed, then photons are EM waves :D :D As I know duality (particles can behave as waves and vice versa) have not dead yet (or he died and I found out?).
Cecil said: "When the concept of displacement current was invented, nobody
knew that RF fields were actually made up of particles (photons) but now we do know". Cecil seem to me as Zarathustra has declared: "¡Wave is dead!" :>)

Yes, yes, I know some people bring very strange ideas into the forums, but I think it is not necessary argue them with exotic others -even if they are true- because the partner will double the bet and will bring other even more bizarre yet...! :>)

Well, dont be bothered by my comments, I am joking a little...

Keith obviously understands the requirements for energy flow, but a casual reader might draw the wrong conclusions. . .

Keith Dysart wrote:
> . . .

> This is quite incorrect. Energy flows must balance, otherwise energy
> is being created or destroyed to sustain a difference in flow.

On the average, yes. But not moment-by-moment. Energy can be stored and retrieved from storage, resulting in unequal energy flow (power) into and out of a point. For a while. This was explicitly stated earlier when discussing a capacitor, but I think it's important to make the distinction here between instantaneous and average requirements. In steady state, the average condition (energy flow balance) must be met each cycle. That is, the total energy into a node over a cycle has to equal the energy out of a node over a cycle.

No, it doesn't, unless I'm misunderstanding the statement. At a given instant, more energy can flow into a component (e.g., a capacitor or inductor) than is flowing out, or vice-versa. But in steady state, whatever flows in during one part of the cycle must flow out during the remainder of the cycle.

Again, only on an average or steady-state cycle-by-cycle basis. Great inequalities can exist for shorter periods.

>. . .

Like Keith, I firmly believe that an instantaneous time-domain analysis is essential in understanding what really happens to the energy in an AC system. Averaging reduces the amount of information you have -- if all you know is the average value of a waveform, you have no way of going back and finding out what the waveform was, out of an infinite number of possibilities. If averaging is to be done, it should be done after you calculate and understand what's going on at each instant, not before you begin the analysis.

But it's also essential to make absolutely clear what conditions must be met every instant, such as p(t) = v(t) * i(t), and which must be met only on the average, such as energy in = energy out.

Photons are very useful in the analysis of transmission lines. They can be brought into the discussion to divert it from taking a path that makes a participant uncomfortable. If unable to answer a question logically, simply toss photons, optics, quantum mechanics, aether, and other confounding factors in, and presto, people will begin arguing about the spurious concepts and forget that you've avoided answering the difficult question. It's called misdirection, a time-honored technique used by politicians and prestidigitators as well as promoters of pseudoscience.

Hi Miguel,

Power? Energy? One second? Choose one to talk about, and perhaps
the mystery of numbers might clear up.

>one quanta an two quanta

Quanta? Two Quanta? We are now up to four intermixed terms.
Simplify. Choose one thing.

>of 80 m radiation is 2.3 * 10^ -27 J, that
>difference (my physic book say) it is unmeasurable experimentally
>(this energy leap (skip?, hop?) it is in the order of 10^-8 smaller
>that green light leap

True, but immaterial. You are confusing wavelength and quanta (no
surprise given the blearing of topic). Compare Green and IR. Is
there a correlation on a scale of two that predicts out to a scale of
10^8? Compare Green and deep IR. Is there a correlation on a scale
of ten that predicts out to a scale of 10^8? Compare Green and the
Sub-millimeter band. Is there a correlation on a scale of 100 that
predicts out to a scale of 10^8?

> (in reality my book -Resnick Halliday- give a
>moving dust particle example with quantic number very much lower than
>my 80 m example yet => n = 3 * 10^14, they said "we can not
>distiguish energy difference among n = 3 * 10^14 and n = [3 * 10^14]
>+1")

So a quantum of smaller energy of a dust particle is measureable but
80M transmission is not? Common sense is wheezing in this dust.

OK, so they are talking about the difference in quantum, not energy.
Would it surprise you that you cannot even tell the difference between
one quanta of green light and two with conventional detecting
technology?

>What it is the ohysical sense of working with magnitudes we can not
>measure? Nobody (as we know) use (or need) quantum mechanics to deal
>with (or explain) locomotive movement :>)

The limitation is called Quatum Efficiency and the human eye is vastly
superior (to all but $1,000,000 components) at rougly QE = 50%.

2838. What could i do with this dish?

Newsgroup: rec.radio.amateur.antenna

Source record: 8688

Hi, i have a 2.4 metre solid dish here and was going to use it for TVRO but havn't got round to it as the majority of it is foreign with subtitles and that doesn't impress me all that much. Just wondering how i might be able to utilise this dish in the HAM scenario. I am a "Standard" licence in Australia which entitles me to transmit on most bands excluding 3776 - 3800, 50 - 52 MHz, 420 - 430 MHz, 2300 - 2302 MHz, 3.5 gig, 10gig, and above. Also can't use WARC bands. So it's a bit limited in the higher part of spectrum but just wondering if someone could offer some suggestions on what i could use it for (Except birdbath, fishpond etc lol)

Thanks

Gary

Ok... could you please explain me how i can build an, e.g., electrical half
wave for the 20 meters in a 3 meters stick ??

I repeat, i'm a great newbie on antenna theory and related arguments, so the
question i pose to you now is not ironic but really posted to increase my
knowledge, if is possible.

Thanks in advance also to other people that may contribute to this question.

"Electrical half wave" doesn't have much meaning when applied to an antenna, so there isn't a good answer to your question. There's no way to make a short dipole behave exactly like a half wavelength dipole in all respects. But if you mean you want to make a short antenna resonant (one of the properties of a physically nearly half wavelength dipole), you can make it or an antenna of any physical size or shape resonant by putting an impedance transforming (matching) network at the feedpoint. Presto, a resonant antenna. If you want the same feedpoint resistance at resonance as a physical half wavelength antenna, you can get that too by adjusting the network component values. The pattern of a dipole of any length shorter than a half wavelength will in practice be indistinguishable from that of a half wavelength dipole. What will happen is that you'll have increased loss due to the larger currents and voltages in the shorter antenna and the matching network, the amount depending on the design. And if the losses are kept reasonable, the bandwidth of the shorter antenna will be narrower than the bandwidth of a half wavelength antenna.

The short explanation is "reactive loading".

The simplest way to achieve what you're looking for, is to take a three-meter stick, and wind it with a spiral of wire. The wire should be insulated, to prevent adjacent turns from shorting together. You would feed the antenna in the center, just as if it were a full-sized half-wave dipole.

The exact number of turns required (and thus the total length of the wire you'd need) can probably be calculated, but I lack the detailed information to know just what the calcs are. I'm sure that there are examples shown on the Web, and/or in the ARRL Antenna Compendium books. You can see one example of this approach at

http://www.w0ch.net/travel_antenna/travant.htm

There are a bunch of design alternatives, divided roughly into

(1) Wind the wire evenly along the whole length of each half of the shortened dipole.

(2) Run the wire straight along the pole for part of the way from the center to the end, and wind turns over the rest.

The "travel antenna" is of the latter sort - it puts most of the added inductance (the coiled turns) down near the feedpoint. He designed it as a shortened quarter-wave, but you could take two of these and stick them back-to-back and have a shortened half-wave.

If you measure the resonant frequency of this shortened half-wave and find that it resonates at too low a frequency, then you've got too many turns... remove some and run the wire straight along a portion of the pole (or space all of the turns further apart). If it resonates at too high a frequency, you need more turns (more inductance).

The behavior of this sort of shortened dipole will be similar to that of a full-length dipole, with several differences:

- Slightly less directional gain

- Higher electrical losses in the dipole

- Lower radiation resistance

The latter two factors result in a loss of electrical efficiency... more of your transmitter power turns into heat in the antenna itself, and less is radiated.

The feedpoint impedance is likely to be different than a full-sized half-wave, too... it may be lower (due to the lower radiation resistance) or higher (due to the additional loss resistance) or nearly the same (if these two factors cancel out).

The approach I've described uses inductive loading - you add inductance in series with the antenna in order to resonate it. Another approach is capacitive loading - you add additional capacitive coupling at the ends of the antenna. This can be done by adding a circular metal "hat" at each end, or a set of radial wires sticking out at a 90-degree angle.

The MFJ antenna under discussion actually uses both techniques - it has an inductive loading coil, and a "capacity hat" of wire spokes, at each end of the antenna (actually, one per band that it's supposed to tune). The combination of added inductance, and added capacitive loading, creates the necessary resonance on each band.

Message-ID: <Xns9DA8618BFD562nonenowhere@61.9.191.5>
Source record: 8692

Considering the steady state...

If we accept the P(t) is the product of instantaneous voltage and current, then there will be some points on any mismatched line where P(t) is always positive. In between those points, P(t) will have positive and negative excursions.

I think that it is a reasonable interpretation that at those points where P(t) is always positive, then there is never at any instant, a flow of energy away from the load, energy is never exchanged during a cycle across those points, it always flows from source to load.

It may be that energy is exhanged during a cycle at the load end of the line, and it may be that energy is exchanged during a cycle at the source end of the line, but if the line is sufficiently long, there will exist points where instantanous power is always positive, and therefore, energy always flows in the load to source direction at those points.

The notion that a reflected wave in general conveys power over the entire path from load to source is not consistent with the above. This notion is emboddied in common language when talking about 'reflected power', but the language belies the actual phenomena.

Owen

Dear Richard:

On examples we usually start with a visible common data, here I made with a 100 W TX power during one second to gives certain amount of energy, this amount of energy stored in a system (for example a LC tank) gives the quantic number of the system. well... Energy it is Power * Time and n=E/h*v, it easy, it is an electrical cuasi identical example as page 1616 part II Spanih translated Resnick & Halliday book. if for Resnick & Halliday guys is a good example for me is good too :>)

I do not confussing wavelengh with quanta!, quantized energy it is E=nhv and v it is 1/lambda, how do you calculate E without v in such equation?
I don not believe my translations are too wrong! I wrote what book say => "they said "we CAN NOT DISTINGUISH energy difference among n = 3 * 10^14 and n = [3 * 10^14] +1"), (page 1652 op.cit.); where you read: "quantum of smaller energy of a dust particle is measureable"? my text says just the opposite!

You say: "OK, so they are talking about the difference in quantum, not energy" I do not know if I am translating well your sentence... perhaps you refer to my missuse of the latin word quanta (plural) instead "quantum" (singular) (in spanish we usually say "cuanto/ cuantos" -not latin-, in english I believe you use latin, sorry by my translating error), but I think not is that.
Quantum in this context is "energy quantum", they are talking about difference of energy, that difference it is not continuos but quantized, and each energy quantum is 2.3 * 10^ -27 J, one quantum, two quantum... n*quantum, n*quantum in the system = E (op. cit. page 1615), what is wrong?

I am talking about 80 m technically useles quantum treatment, and you say to me: "The limitation is called Quatum Efficiency and the human eye is vastly superior (to all but $1,000,000 components) at rougly QE = 50%."

What sort of human eye we use to see 80 m "light"? :>)

I did not want go out off topic, I claimed quantum mechanics do not help so much to solve TL related problems and give some reasons for that. I am not an expert in quantum physics and I am not going further that my elementary physic book examples. Are they wrong? well... then, I am wrong too :>) PSE do not argue with me, I am innocent of charges, read the references...

I'd make a small addition, that . . .there is never at any instant a
net flow of energy away from the load. . .

The problem is that I don't know of any way to keep track of a
particular bundle of energy -- it gets mixed together. So you could have
energy constantly flowing both ways through a point while maintaining a
net flow (power) in one direction and it would look just the same as
energy going only one way. Keith's DC thought experiments illustrate
these different approaches and some of their logical -- and illogical --
consequences.

Quite some time ago I wrote and made available a little graphic program
showing the voltage, current, power, and energy on lines under several
conditions. When a complete standing wave exists, there are points of
zero voltage and current and hence zero power. For one half the cycle
you can see energy moving into those points equally from both directions
(obviously being stored at the node), and during the other half, energy
is moving out of those points in both directions (being retrieved from
storage). One interpretation is that the energy arriving from the left
exits to the right, and vice-versa, and that fits neatly into the
concept of waves of energy simultaneously moving in both directions. Or
you can decide that the energy which came in from the right exits to the
right, and in from the left exits to the left. If that's your
interpretation, then you conclude that no energy ever crosses the
boundary. I think this is the genesis of Cecil's view that energy waves
somehow bounce off the standing wave node. Both interpretations fit
equally well with the observed net flow of energy but, like Keith's DC
thought experiments and Cecil's writings show, take you down quite
different paths when trying to divine some concept of what's
fundamentally happening.

it would probably be good on the 2300mhz and higher bands. not sure
about how good on 70cm it might be off hand. 10ghz is very popular
here in the states, it even has its own contest. you should probably
try to contact some local microwave guys there and see which bands
have the most activity.

Hi Miguel,

POWER. Please observe the distinction as appeals to 100W or "one
second" have no bearing on where you seem to be fixated with quanta
and energy. Introducing distractions is not very useful. [I can
appreciate that you are not the source of the distractions.]

>I do not confussing wavelengh with quanta!, quantized energy it is

Then quanta is a distraction, or wavelength is.

>What sort of human eye we use to see 80 m "light"? :>)

Why do you compare 80M to green light? The more wavelength
appropriate scale would be invisible in the 800nM Infra Red or in the
80nM Ultra Violet. Green light's correlative would be in the 55.5M
band (tropical SW).

>I did not want go out off topic, I claimed quantum mechanics do not
>help so much to solve TL related problems and give some reasons for
>that.

Indeed, no doubt this [distraction] is attributable to a Texas
[distracting] snake in the grass.

Quantum mechanics can give a certain perspective and sense of scale,
but [distracting] amateurs shouldn't try that at home or on the
Internet.

> I am not an expert in quantum physics and I am not going further

The Cosmic Radiation Background has been measured to about 2.76 K,
where the mapping variation (fluctuations of 30 microKelvins) are
within the Energy perturbation (contribution) of our Amateur
transmissions.

So as to not argue, I firmly agree with you that no one is going to
find any utility in any of this. But the debate will rage on
heedless.

> Roy Lewallen, W7EL

That reminds me that somewhere in the morass of this thread, I believe
I saw an "exchange" about whether it was more proper to think of a TEM
line in terms of inductance and capacitance, or in terms of (electric
and magnetic) fields. I suppose someone had lost sight of the fact
that capacitance is simply a model that relates energy stored in an

electric field to the applied voltage, and inductance is simply a model that relates energy stored in a magnetic field to the conducted current. How easy it seems for some to become so invested in a particular viewpoint that they can't see that other viewpoints are equally valid (and often just a different way to say the same thing) -- and may on occasion lead to new insights. Of course, those viewpoints that have little to recommend them don't have to be given a particularly prominent position in our thoughts. Far be it from me to say that 10MHz energy isn't quantized, but since the quanta are far too small for me to measure, I seldom give them much thought.

Cheers,
Tom

2849. Crossposting Permitted to rec.radio.amateur.moderated

Revision: 1.1 2009/04/12 19:42:04
Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35
f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. We are currently trying
this on a temporary basis (90 days, through early July 2009), and adopt
it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.

Each wave transports the mass and energy from the source (or mirror).
In the microwave oven the all energy is transfered into heat.

In antenna the part of energy and mass is emitted. The reflected part is
smaller.

A helically-wound dipole or monopole that is physically short in terms of a free-space wavelength can be made electrically resonant at its input terminals as a result of the inductance of the helical form of the radiating conductor.

But that does not mean that it has all of the electrical characteristics of a linear conductor that is inherently resonant, without the need for inductive loading.

The radiation resistance of such a helically-wound radiator can be much lower than a naturally resonant radiator, which can mean that the percentage of transmitter power radiated by the antenna SYSTEM can be much lower than when a naturally resonant radiator is used.

The link below leads to a page developing this point from Kraus' Antennas For All Applications, 3rd Edition.

If the cosine term is zero, there are zero EM waves, either forward or reflected, and your argument falls apart.

Incidentally, V(t) = 10, is a perfect way to prove that energy and the time derivitive of energy are not the same thing and your argument falls apart.

Windowing doesn't generate EM waves where none exist in reality and your argument falls apart.

a better argument is that a constant voltage produces a constant
electric field everywhere, since the field is not varying in time or
space there is no time or space derivative to create a magnetic field
so there can be no propagating em wave. you could do the same with
zero or constant current producing a constant magnetic field.

essentially the dc case IS unique in that you must wait forever for it
to reach sinusoidal steady state since the lowest frequency component
is 0hz.

Yes, replying to Richard but also to Roy and Dave.. maybe i can't explain
very well, but the sense of my latest question is this:

if a half wave end-fed *monopole* antenna have the following primary
characteristics (if IIRC):

- High Z at the feedpoint (voltage maximum and current node);
- very small counterpoise lenght compared to the resonant wavelenght of the
antenna (typical 0.1-0.2 lambda)

can i mantain the same characteristics shortening the antenna in any way ??

Thanks for read and explain to those who want clarify my doubts.

One too many words - what I meant to say is that you are not adding up the energy - you are adding up the power. There is no such thing as conservation of energy flow. That is proved by your own graphs. There are times when the energy flow is destroyed. There are other points on your power graphs where energy flow is created.

> There is no conflict with conserving flows, ...

The conflict is that conservation of flows doesn't exist. Keith, you need to go back to college. There is no such thing as conservation of energy flow so your argument falls apart. When one looks up "conservation" in a physics book one finds:

conservation of energy principle
conservation of mass-energy
conservation of mechanical energy
conservation of momentum principle

There is NO conservation of energy flow or conservation of power. Until you give up on that ridiculous concept, we don't have much to discuss except your religion.

> > What happens when energy = 1 joule, and de/dt = 0 watts. This happens

> > flows. You are using power which goes to zero even when maximum energy
> > is still present.
>
> Yes, indeed. That is a fundamental possibility and occurs on
> transmission lines with infinite VSWR.

If power goes to zero, power has been destroyed. Therefore, there is no conservation of power principle. Anything that can go to zero, i.e. can disappear, cannot be conserved.

> Power is the time derivitive of energy. They are related
> but definitely not one-to-one.

Well, that shoots your argument down. If power and energy do not have a one-to-one correspondence, then you cannot use the conservation of energy principle to prove that power is conserved and your argument falls apart. You must then product a conservation of power principle, something that every physics professor has warned us doesn't exist.

I can provide any number of references to support the conservation of energy principle. Please provide just one bona fide reference that supports your conservation of energy flow (power) principle.

> This is quite incorrect. Energy flows must balance, otherwise energy
> is being created or destroyed to sustain a difference in flow.

Good grief! Any physicist knows that is false. Any number of examples prove that is false.

> Energy flows must balance as well. Otherwise,
> energy is coming from nowhere to sustain the flow.

Given a black box with an input and output. Measurements of the power flow vector indicates that the magnitude of each power flow vector is 50 watts and both vectors are pointing inside the black box. How can the instantaneous energy flows possibly balance?

> Instead, think that at every instant, the energy flow between the
> entities in the experiment must balance.

You are contradicting yourself. Assume the capacitor *IS* the system inside a black box. The instantaneous energy flow does NOT balance.

> It is the
> total energy within the system that is conserved, just as it is
> the total of the flows of energy between the entities within the
> system that must be conserved.

You have it half right. Energy must be conserved. Energy flow is not conserved.

> Put more strictly: The sum of all the energy flows in to all of
> the entities within the system must equal the energy flow in to
> the system.

Please see the black box experiment above and balance the energy flow.
Please produce a reference for the conservation of power principle.

Translation: Don't bother me with technical facts based on the laws of physics. I am perfectly happy with my present metaphysics.

Actually, recognizing that EM waves are photonic in nature and are therefore bound by the laws of physics governing photons is an attempt to correct the previous years of misdirection engaged in by some RF gurus. Such concepts as zero energy in EM reflected waves comes to mind. If EM reflected waves do not obey the laws of physics, then they don't exist - but they do.

I'm sorry, Roy, but I never said anything of the sort. Keith
apparently believes that energy waves somehow bounce off a standing
wave node. I am on the opposite side of that argument. I believe that
the forward wave and reflected wave flow right through a standing wave
node. I am on record as saying the only time a reflection occurs is at
a physical impedance discontinuity.

Misdirection is also accusing someone of saying something that they
never said, is a low blow, and is not an ethical act.

> can i mantain the same characteristics shortening the antenna in any way ??

With proper design you can maintain the resonance characteristic with that short antenna, but not its characteristics of SWR bandwidth, exact radiation pattern (directivity), or radiation resistance.

For a single frequency the only important difference will be radiation resistance, unless the short radiator is used with a virtually perfect (zero loss) ground plane.

A typical r-f ground loss even in a set of 120 each, 1/4-wave-long buried radials is on the order of two ohms. So referencing the example in the link to Kraus that I posted earlier, the radiation efficiency of that helically-loaded monopole system with a two ohm r-f ground would be about 0.6/2.6 = 23%, approximately.

The loss of a radial system using 0.1-0.2 lambda conductors would be significantly higher, so the antenna system radiation efficiency then would be significantly less than 23%.

A naturally-resonant, unloaded monopole about 1/4-wave high has a radiation resistance of around 34 ohms. When it is used with a two ohm r-f ground, the radiation efficiency of the antenna system is about 34/36 = 94%.

Free electron laser it is a quite different thing than laser.

The free electron laser produces the "laser-like" light:

" As the electrons are undergoing acceleration they radiate electromagnetic
energy in their flight direction, and as they interact with the light
already emitted, photons along its line are emitted in phase, resulting in a
"laser-like" monocromatic and coherent beam". From:

I do my best.

May be the Wiki is better: "The electron temperature of a plasma can be
several orders of magnitude higher than the temperature of the neutral
species or of the ions. This is a result of two facts. Firstly, many plasma
sources heat the electrons more strongly than the ions. Secondly, atoms and
ions are much heavier than electrons, and energy transfer in a two-body
collision is much more efficient if the masses are similar."

You know: The Sun produces the plasma (it rotate with the Sun) and the
plasma is a medium for the longitudinal electric waves (Tesla - the father
of the radio). Is not it funny?

But a helically-wound radiator *is* a naturally resonant radiator if
wound to make it so. It just isn't straight.

Although 2 ohms is a reasonable approximation for 120 radial ground system resistance, it varies not only with ground quality and frequency, but also antenna height. For example, an NEC-4 simulation for vertical radiators at 3.7 MHz with 120 radials, each a free space half wavelength long buried 0.1 meter in average soil, shows 3.25 ohms ground system resistance when the radiator is 0.24 wavelength high (nearly resonant). When the radiator is shortened to 0.12 wavelength, the ground system resistance increases to 4.30 ohms. And with a 0.06 high radiator, the ground system resistance nearly doubles to 8.06 ohms. This decreases the efficiency of the very short radiator by about an additional 3 dB beyond what it would be if the ground system resistance were fixed at 3.25 ohms.

I believe the ground system resistance increase with short radiators is due to concentration of the field very close to the antenna, resulting in much higher ground currents in that region. It would probably be useful to use a larger number of radials, which could be shorter, when the radiator is very short.

You can add a top hat to a vertical that's shorter than a half wavelength, and bring it to anti-resonance (high input resistance with no reactance). The impedance won't be as high as if the antenna were a half wavelength high, and it will have narrower bandwidth, so it won't be a perfect imitation. Or you can use a combination of loading inductance and top hat to get a somewhat poorer imitation.

That is true, but a resonant, helically-wound, electrically short radiator does *not* have the radiation resistance of a straight, self-resonant radiator of about 1/4 wavelength -- which can make a large difference between the two forms in the amount of available energy radiated vs. that lost in the r-f ground system.

Guess I just don't understand how a resonant, helically-wound antenna is "electrically short". Suppose you helically wound an eighth-wave vertical in such a way that it was resonant. Its physical length is an eighth wavelength. What would its "electrical length" be? That is, how "electrically short" would it be?

How do you determine what the "electrical length" of a vertical or dipole is? Does a loading coil at the base alter the "electrical length"? Does an L network at the base?

Its overall height in free space wavelengths. This is the definition
used by the FCC for the unloaded monopoles used in AM broadcasting

Do you expect your 1/8 WL high, self-resonant helical to have the same
electrical length and feedpoint parameters as a self-resonant,
straight radiator about 1/4 wave high in free space wavelengths?

According to Kraus and other authors, your example above still has
about the same radiation resistance as a 1/8 WL straight conductor --
not that of a self-resonant, straight conductor about 1/4 WL high.

An 1/8 WL high helical may be resonant, but it will not perform the
same in a practical antenna system as a straight, self-resonant
vertical whose physical height in free space wavelengths is about 1/4
wave.

Oh, then the "electrical length" is the same as "physical length". Why not just say "physical length" then?

> Do you expect your 1/8 WL high, self-resonant helical to have the same

You just said that the height of the antenna is the electrical length. So no, I wouldn't expect two antennas of different heights to have the same electrical length, using your definition.

> According to Kraus and other authors, your example above still has
> about the same radiation resistance as a 1/8 WL straight conductor --
> not that of a self-resonant, straight conductor about 1/4 WL high.

It'll be a little higher than a straight 1/8 wave conductor due to a bit more favorable current distribution (see the article referenced in my next paragraph for some actual measurements). But it'll surely not be as high as that of a quarter wavelength conductor. Which of course is the reason it's so important to minimize loss if you want good efficiency.

> An 1/8 WL high helical may be resonant, but it will not perform the

Depends. If the ground system is very good and you're willing to keep to a narrow bandwidth without retuning, you wouldn't be able to tell any practical difference between the two. For good experimental evidence see "The W2FMI Ground-Mounted Short Vertical" by Jerry Sevick, W2FMI in March 1973 QST.

Unfortunately, I understand completely.

Laser = "laser - an acronym for light amplification by stimulated emission
of radiation"

Laser rework natural light (radiation).

Antennas produce artifical radiation in the result of the electron
oscillations.

To make the oscillations we use different devices.
LC for radio waves, megatrons for microwaves, claystrons for radar waves and
the Halbach array for the light frequency.

The word "laser" is probably common name for the all atificical light
sources.

Is there a shortage in the supply of coax ? A ham up the road has been trying to get some rg8x from The Wireman for a couple of weeks. They are out and said they should have some in soon.

There was also some mention of shortage of the open wire\twinlead type.

Is it just this place or is there some shortage in the US of coax and antena wire.
What about the other coax such as the rg8 size ?

No, it is not. From answers.com: "Definition: laser - Any of several devices that emit highly amplified and coherent radiation of one or more discrete frequencies."

From Wikipedia: "Light Amplification by Stimulated Emission of Radiation (LASER or laser) is a mechanism for emitting electromagnetic radiation, typically light or visible light, via the process of stimulated emission. The emitted laser light is (usually) a spatially coherent, narrow low-divergence beam, that can be manipulated with lenses. In laser technology, 'coherent light' denotes a light source that produces (emits) light of in-step waves of identical frequency, phase,[1] and polarization. The laser's beam of coherent light differentiates it from light sources that emit incoherent light beams, of random phase varying with time and position."

should we even bring up its close cousin, the MASER? I particularly
like this definition:

"MASER stands for Microwave Amplification by Stimulation Emission of
Radiation. A LASER is a MASER that works with higher frequency photons
in the ultraviolet or visible light spectrum"
from: http://einstein.stanford.edu/content/faqs/maser.html

According to something I read, the MASER, which was introduced while I was still in high school, was the original idea behind the development of the LASER. Thanks for your reference which says: "Basically, a man-made MASER is a device that sets up a series of atoms or molecules and excites them to generate the chain reaction, or amplification, of photons."

What??? A MASER is an RF devices. When discussing RF, aren't photons just a diversion away from "The Truth According to the Great RF Gurus"? Someone should tell the MASER guys that they are just wasting their time associating their RF devices with atoms and photons when they really should be using fields and waves to explain the MASER phenomena. Good luck on that one. :-)

Yes, but all is not lost. You need to get the newst Ham in the neighborhood and send him out for a coax stretcher. They come in handy from time to time.

I have to admit I never found one in my neighborhood - but all the Hams were very helpful and thought they knew who might be able to help me, and sent me off to the person.

Hello Richard:

(I am not quoting with ">" because I get unpredictable results with google :>))

You said: "Please observe the distinction as appeals to 100W or "one second" have no bearing on where you seem to be fixated with quanta and energy."
I could not translate this sentence, (sometimes your writings are complicated for me Richard, try Tarzan style or better yet... try as you were writing to Cheeta! :>)
(I handed the sentence to a friend who lives in England and today said to me that have so many interpretations and did not solve my problem...)

"Why do you compare 80M to green light?"

Well... I like it! photons born from light, green light it is a central zone of visible light spectrum, and 80 m is my favourite ex-novice band...
Look, light has a very rough "texture", light quanta is a very energetic thing, its "granularity" it is high and we easily perceive its quantic nature, 80 m energy instead has a very, very "soft" texture, 10^8 time softer than green light, and we can not measure its "granularity" with our instruments. Think of a 1000 kg car smashing against your car at 100 km/h, now think of a mosquito (10 mg) smashing against your windshield at the same speed.. well if the one green light quantum had the cinetc energy of a 1000 kg thrown against your car, 80 m quantum would have the mosquito energy! It is a really good example... you should congratulate me for that formidable approach!! no?, hi hi

Physicists said that we can better perceive energy glanularity at lower temperatures and they say we have classic behaviour when hv << kT, well... at 1 K, kT it is 6000 times bigger than 80 m hv, a very classic oscilator indeed!, at 293 K ambient temperature I think we can not appreciate quantized nature of RF waves!, (at least with my Bird 43) :>)

I have a question too, please tell me (I am very curious): why you take every opportunity to bite (sting?) my friend Cecil, ah? ;>). I read carefully Cecil writings and I do not find flawings in his affirmations; usually he is very precise and scholar on this matters,

sometimes he has an occasional forgivable habit, such his predilection for photons and polished glass things, but I think he has not so "distractive", usually I understand wiich is "his point" to bring another physics areas on the table... I think often we have a little stubborn too :>D

73, and thank you very much for your company - Miguel - LU6ETJ

You should add: "Basically, a man-
made MASER is a device that sets up a series of atoms or molecules and
excites them to generate the chain reaction, or amplification, of
photons."

Laser and maser reworks the light produced by atoms or molecules.

In the Halbach array no atoms or molecules.
There are working only the electrons in vacuum. Like in transmitters,
megatrons and claystrons.

>novice band...

Yes, green (actually green-yellow) light corresponds to photopic (day)
vision. Scotopic (moonless night) vision is blue-shifted. Sitting
inside would tend towards a combination called mesopic vision.

The analogue of the eye as "receiver" gives us the peculiar action of
resonance shifting due to strength of the QSO. Propagation fading
would find the contact drifting from the 80M Band up through the 60M
band.

>Look, light has a very rough "texture",

Is Cheeta trying to say photons?

>light quanta is a very
>energetic thing, its "granularity" it is high and we easily perceive
>its quantic nature,

The eye can sense one photon out of two under the best of conditions, but what that means as far as "granularity" is lost on me. A RADAR (even if not an 80M one) can respond to a pulse it sends and senses in an echo. The packet contains at least 100 to 10000 cycles. Pulse shape signatures would suggest that individual cycles are resolved - granularity?

>80 m energy instead has a very, very "soft"
>texture, 10^8 time softer than green light, and we can not measure its
>"granularity" with our instruments.

The granularity can be expressed in microKelvins of temperature which can be (and has been) resolved. What you describe as "we can not measure" is more a function of background noise, not ability, nor instrumentation incapacity.

>Think of a 1000 kg car smashing
>against your car at 100 km/h, now think of a mosquito (10 mg) smashing
>against your windshield at the same speed.. well if the one green
>light quantum had the cinetc energy of a 1000 kg thrown against your
>car, 80 m quantum would have the mosquito energy! It is a really good
>example... you should congratulate me for that formidable approach!!
>no?, hi hi

Analogies, as we have mulled them over in the past, often lead to their own failure and that, in turn, brings down the central point trying to be argued.

Case in point with your mosquito: The two collision events can also be expressed as energy translation into temperature change. This is called phononic energy - or sound. The crash of cars or bugs resolves into a sound. Do we hear, or do we have the capacity to hear either? Both? There are 8 orders of magnitude difference between the two masses at the same velocities. Our hearing dynamic range easily encompasses that. I can hear bugs bump against my living room window at far slower velocity. I would not hear them with the background noise of an operating automobile and the various road, wind, conversational or radio noises raising the noise floor.

This points out that measurement failures are often a matter of method, hence the human component of psychological impairment. Science is more fascinating in its stories of overcoming shortfalls of perception. Einstein wasn't known for his math, or his benchwork, he gave us perspective.

>Physicists said that we can better perceive energy glanularity at

>43) :>)

All the matter of background noise.

>I have a question too, please tell me (I am very curious): why you
>take every opportunity to bite (sting?) my friend Cecil, ah? ;>).

Probably because you enjoy reading it, otherwise why are you offering
another opportunity? ;-)

Hi hi, no, not Cheeta... Resnick & Halliday & Krane use "granularity" metaphor, "granularity" and "texture" are words that denote same idea: ligth photons are really very big Jerry Lee's "Great balls of fire", 80 m photons are very very tiny balls :>) For that reason your eyes catch light photon, they (photons) are fat guys, you know?.
Glanularity is not about "cycles" but quantum energy => hv, v=frequency, high frequency => high energy quantum => high granularity, not cycles

Not "analogies", no, no, I am only comparing energy magnitud differences! (I am not resigning my rights to analogies, with this), 10^8 more bigger cinetic E represents so much energy difference at any scale; obviously a light photon has very, very much lower energy as a 1 t (Tm) car at 100 km/h (it has 3.6*10^-19 J) but 80 m photon it is 100000000 lower!, Can you hear 80 dB sounds below mosquito buzzing? are you the six million dollar man? :>)
You talk about "fluctuations" OK, can you assure to me those fluctuations are due quantized nature of RF signals? have you references about that? Naturally I have my doubts, what you say do not match my sacred Wiley & sons bible physics verses: remember at only 1 K, kt >> hv, and for R, H & K elders, granularity can not be perceived.

Well, but stop here, please: I did not say we can not measure 100 W oscillator granularity, eh?, I am not any authority to say such thing!, look what the fathers of my church say in page 483:
"Quantized energy simply not reveales in large scale oscillators, the smallness of the h Plank component make the granulosity very fine (thin?) so that we can not detect it"
I bet you live a little more near them than I, Ask to them why they said that. I am innocent, I am only the postman who brings the news (where is Petrocelli?) :D :D

73 - Miguel - LU6ETJ

PS: Cecil, friend, this man this is already yours. Just confessed his inconditional love for RF quanta...

I ran in to the same thing last August at the Huntsville, Al. hamfest-
no 450 ohm open wire line. The high cost of copper prohibits them
from keeping too much inventory on hand. Apparently not much has
changed since August.

>references about that? Naturally I have my doubts, what you say do not
>match my sacred Wiley & sons bible physics verses: remember at only 1
>K, kt >> hv, and for R, H & K elders, granularity can not be
>perceived.

It isn't their field, but that doesn't mean science is invalid. Google
the terms (you already have one in quotes). This has been around for
a decade or more.

>"Quantized energy simply not reveales in large scale oscillators, the
>smallness of the h Plank component make the granulosity very fine
>(thin?) so that we can not detect it"

The problem with selective quoting is that the reader doesn't know the
boundaries - aside from it being a paraphrase and not a literal quote

- unless they write like Cheeta. Sorry for the allusion to a monkey, but the grammar reveals this is not a true source. I can read between the lines, but then I get to expand upon that to introduce my own spin. That doesn't get things very far, does it? Don't pick up on Cecil's bad habit of leaning on the Xerox copy button.

>I bet you live a little more near them than I, Ask to them why they
>said that. I am innocent, I am only the postman who brings the news
>(where is Petrocelli?) :D :D

Why don't I? The price of email is the same from any location on earth (or through a satellite link freely accessible from outerspace).

Somewhere back in time the word "aperature" was used to describe
antennas, especially stacked arrays. I think one of the prominate
authors that used the expression was Bill Orr.

Would that be relevant to this discussion? I have not heard the term
used in years.

If the ratio of the conductors stay the same, there should not be a change except the losses go up. As you streach the coax, the shield and the center conductor will get smaller. Also the dialectric will have to get smaller. If they do not srink at the same ratio, the impedance will change depending on which conductor gets smaller the fastest.

The losses will go up because the center conductor and the outer conductor are smaller. This is the simple IR loss of the conductors. It is the same as going from a rg-8 to a rg-58 type coax.

Walt-

Contact Tucker Electronics to see if they are willing to deal!

One such device is the General Radio 874LK20L line stretcher. Tucker
may have them in stock. See
<http://www.tucker.com/java/jsp/product_partno874LK20L_invid17338_condR.h
tm>.

The product is described in a GR document at
<http://www.tucker.com/images/images_spec/00001006.pdf>. It is supposed
to have a constant impedance.

Hi,

I tried a shortwave radio group first, but no answers.
Should have posted here, first.

Enjoy sw listening, but frankly not all that sharp re antennas.

Over the past few months, I have seen several ads for those handheld sw
receivers and transceivers. From different mfgs.
About the size of the typical hand-held scanner receiver.

They all seem to cover up to at least 30 MHz, and most beyond.

Got to thinking about this a bit.
What do they use for an antenna for 30 MHz and below ?

I have a long end fed antenna for my listening.
Obviously they have a short "something" antenna.

How effective is a short "something" around 5 to 10 MHz, e.g. ?

How can it work down there at all ?

I can visualize s tuned ferrite loop, such as the very old fashioned AM
table radios used to have, but wouldn't this only be effective over a
very small range ?

Or, do they expect you to hook up something "decent" to it, even though
it is supposed to be portable, and is very small ?

Any technical explanation on this would be most appreciated.

Thanks,
Bob

Hi Bob,

A make and model number would get you a more definitive answer.
However, for the broader question, and as you undoubtedly expect, more antenna is better - to a point. Some will argue, theoretically, otherwise. I go with results.

When I was in South Africa (no, not the World Cup), I took along one of Radio Shack's cheapest SW radios. It had the conventional whip, and it offered the conventional whimp. However, having foresight, I also took along about 20 feet of wirewrap wire with a quarter taped onto one end. At the close of day, I would wrap one end around the shortened whip and I would toss the quarter into the rafters (we stayed in thatched covered huts), all of a ten or fourteen foot height; and signals came booming in from all over the continent and Europe.

Another thing missing from these small jobs are a tuned front end. In fact, you can spend a lot of money on SW radios and still not get front end tuning. A preselector, or simple antenna tuner (as cheap as one as you can find, or build one for $10) will go far, far, far.

I seriously doubt if there is any shortage of copper for coax or any other type feed line. It's probably more a matter of someone forgetting to order stock, or enough stock. Or, like gasoline, it's a contrived 'shortage'.

As for a 'coax stretcher', all is not lost, I have one. No, I do not loan it out. I might be talked into selling it, but you probably couldn't afford it, sorry.

Hi, hi, I do not quite understand/translate your jokes: do you dislike Resnick's "granularity"? I think it is a sort of energy acne :>)

You said you could hear an insect shooting your window then I asked you if you can hear sound 80 dB below insect shooting your window. 80 dB example it is only a about difference (quotient) of magnitudes. Or you do not read well or I not write well my sentences -the last has a probability of 0,99- :>)

Certainly, my book is in spanish, the original is "Physics" Vol II, Extended version, 4th ed. ISBN 0-471-54804-9 (I do not have it), read from here. Yes, it is dated 1992 a little old, doesn't it?. so... can we today measure quantum acne from large scale 3,5 MHz oscillator at room temperature? (Use caution to answer me because your words can turn against us and someone may be tempted to postulate "The uncerntainty VSWR principle" and rots all here :>D)

Yes, yes, I by far prefer Xerox button to my own non senses :=D :=D. (another sting to my friend Cecil?).

Well, I stop here because I think our friends are going to reprimand me for not posting serious matters.

Thank you very much for your friendly and patient with me posts .
Miguel LU6ETJ.

Hi Miguel,

Good joke. Others may not be aware that Buenos Aires is one among
cities that have the highest psychiatrist to population ratio in the
world. To set the record straight, Seattle has a very high suicide
rate. This in no way intimates that you are crazy and I am about to
off myself (this may disappoint some that drawl).

>You said you could hear an insect shooting your window then I asked
>you if you can hear sound 80 dB below insect shooting your window.

You presented the analogue of car vs mosquito. You expressed the
magnitude of difference. I disputed neither, accepted them, showed
that the difference(s) could be perceived. Why add a new variable? If
you are not, are you challenging your own analogue?

> 80
>dB example it is only a about difference (quotient) of magnitudes. Or
>you do not read well or I not write well my sentences -the last has a
>probability of 0,99- :>)

You are now extending it to 160dB of difference.

As I said, you either have your magnitudes inverted, or are now mixing
metaphors. The argument is in failure mode. This is invariably the
fate of metaphor/analog/allegory when it is forced to replace simple
math for observable and demonstrable science.

To touch on allegory, the snake in Eden (read Texas) introduced
analogues (read Hallelujah - let there be Photons!) and seduced (read
perverted) logic to obtain mastery over creation (read RRAA).

Don't blame the guy with the horn. :-)

Not too many of us get new copies from the future, so I am not
particularly upset about its copyright date.

Bob-

Like Richard, I have one of the small Radio Shack SW Receivers. I think it was made for them by Sangean. It has a telescoping antenna that may be as long as 36 inches when extended. No, a 36 inch antenna is not as good as a longer wire for Shortwave reception.

Someone with a better understanding of antenna theory may be able to calculate just how much worse it is, but suppose it receives a signal at a 20 dB lower level (1/100th the power level or 1/10th the voltage) than a full-size antenna. All you need is a stronger signal to make up for it. But when propagation is good, signals can be quite strong.

Even so, it wouldn't hurt to take along some extra antenna wire!

Fred

Hi Miguel,

Sorry for the loss in translation. It is what is called "deep
metaphors" that go beyond the simpler ones of mosquitoes against the
windshield.

>I believe what we have more here are psychoanalysts not psychiatrists
>(I read something about it time ago), but do not worry I am a little
>crazy too! :>)

You are correct (about analysts...).

Here, the game of language is found in the ellipsis (or the
parenthetical aside - this one being doubly self-referential).

>Look, my first idea example was compare difference in marbels size
>with hydrogen atom size (about 10^8) to point to granularity, but
>inmediately I realized that dealing with differences in size was not a
>correct example and turn to Ec example. You said our retinas sometimes
>can perceive individual light photons, no?

Yes, in the best of circumstances half of those that impact the
retina. This returns us to background noise and S+N/N.

> then I pointed to an eigty
>meters photon had 10^-8 smaller energy than green photon.

Hence the eight orders of scale comparison. Yes.

>I was telling we are talking about truly classics system therefore
>quantum effects (photon) it is useless because in our level of
>discussion oscillators/transmitters do not manifest quantum effects
>because its very high quantum numbers Of course I know (do I know?,
>really?, mmm) correspondence principle.

You can experience one photon, however could you state that it was not
two instead? I have designed with components that are specifically
photon counters. These are called photomultiplier tubes (PMTs for
short). Where they do not match up against the eye for dynamic range,

spectral bandwidth, or quantum efficiency; they do present us with individual events within a group. Our eyes do not count very well.

>Why at room temperature? Do we see if I understood your question... at
>room temperature because we Hams usually make our TL Bird Truline
>measurements at room temperatures. Answer this your question? (my
>freezer do not go beyond -20 Celcius degrees!).

So, I am to understand that you want to measure quantum effects at energy background levels in excess of 0.04 eV or roughly 10 TeraHertz. I don't think you can afford the Bird plug for that band.

I come from a field called Metrology. This is so rare that many, many engineers have never heard of it. It is the science of measurement. If you want a quantum correlative to frequency, this field abounds in them. The Atomic Clock (Cesium Beam Standard) comes close, but the Josephson Junction is a direct translation of frequency to voltage. It is also an instrument in quantum computing.

I will offer a page for your consideration:
http://www.ptb.de/en/org/2/Inhalte/Josephson/_josephs.htm

Anticipating your objection that the frequencies involved are not in the 80M band; I would offer that is satisfied easily through frequency multiplication. (The Atomic Clock does this in reverse and no one complains about that.)

Anticipating your objection that this is not done at room temperature; true, the junction is cooled far below what is available to you - but is this about your limited resources, or is it about being done? Don't join the legions pleading destitution (poverty) as that might migrate into the metaphors and analogies for a very poor (sorry for the pun) outcome.

>Theorical/extreme
>cases are welcomed too but... to rebut normal/standard situations?
>I do not believe you has blocking Cecil posts, no no, you say it => we
>have a lot of psychoanalysts here: one of them are whispering to my
>ear just now, you really like him, remember TV series: "The odd
>couple"? :>D

Yes, I do block him. There are traces that sift through the cracks, but that doesn't elevate them to poignancy. Again (do I have to repeat this?), this is about S+N/N.

"The Odd Couple" is a good cultural reference. I would suggest (and I hope you have access to) "House." Cecil is among those who cannot be trusted to write on the white board.

If you don't have TV access to this series, try an episode from:
http://www.hulu.com/search?query=house&st=0
You write and understand English quite well, but if listening to it is not easy, I am sure that watching 10 minutes around that white board

will give you enough "body language" to translate the psychology
easily.

>.....
>(You see?, I'm lost with some interesting sentences such "However your
>VSWR may vary, no Standing Waves were interfered with in the making of
>this response." If tomorrow I find my london friend I ask his helping
>to translate better your entire post :>))

This might be lost on your English friend too, because it constructed
with cultural references (it is suppose to be bad form to have to
explain a joke - but here we go):
"However your VSWR may vary"
is a variant on YMMV that you may see as shorthand. It means Your
Mileage May Vary. It is a reference to how car gas performance was
reported by those who sold cars. They would quote government tests
that were generally optimistic, and the real experience would
disappoint customers who saw poorer results. The customers would
complain to the vendor. Thus the vendor would qualify with "the
government reports this car gets 50MPG on the Highway - but your
mileage may vary." Thus the usage of YMMV is a cultural joke
indicating disappointment was likely.
" no Standing Waves were interfered with
in the making of this response."
is a variant on the disclosure you see at the end of movies:
"No animal was harmed during the filming of this movie."
You will, no doubt, draw out the meaning of Standing Waves,
interference, and response as being related to soothing those people
who cry uncontrollably when they see the movie "Bambi." We have a
similar class of sob-sisters (your English friend should be able to
translate that).

There was a long discussion here about using compression type F connectors (and BNC) with RG/6QS coax recently. I suggest that you look it up and refer your friend to it.

The general consesus was that RG6QS was a pretty good choice for amateur use. Not the best, but for the usual low power setup, it was ok.

There is RG6QS coax designed for satellite downleads (1-2gHz) so if you get that it should work for 900 and 1296mHz, possibly 2.4gHz.

It is very important to note that we were talking about COMPRESSION connectors, which compress from front to back sealing the cable in, and NOT crimp on connectors, which are squeezed from side to side and often fall off.

Geoff.

Usually known on the business as 'Snap and Seal' (or 'Snap-N-Seal',
'SNS' etc) connectors. This type is now the only type used in most of
the UK cable TV industry (and, no doubt, in the USA). They are very
difficult to pull off, and are essentially watertight.

For example:
http://www.wittenberg-antennen.de/snapnseal.pdf
<http://www.3starinc.com/lrc_sns11as_snap_n_seal_rg-11_cable_f_connector.
html>

You do, of course, need the appropriate tool.

>and NOT crimp on connectors, which are squeezed from side to side and often

Ian Jackson wrote:
> You do, of course, need the appropriate tool.

They are relatively cheap. I've seen a set of tool, cutter and stripper (3 tools) and 20 F connectors for as little as $12 on eBay. Here, a month ago I paid $60 for such a set without connectors, today when I went to the same store, the tool alone was $30. Last month they did not have the tool alone.

The bad news is that they raised the price on the connectors from $.90 each to $1.25 each, but dropped them to $.77 if you bought 100. They had 2 packages of 50 and to convince me not clean them out, they gave me the 100 price for 50.

>>and NOT crimp on connectors, which are squeezed from side to side and often

From my experience, the tools are more expensive, and the skill level required is much higher to get the done properly. Most of the crimp on ones are not water resistant, while most of the compression ones are.

Geoff.

Actually, human rods can detect one photon but that small impulse does
not reach the brain. It takes about nine photons for our brains to
experience photons. It's a transmission line problem, not a detector
problem.

Thanks for the reply. My friend has been a ham for over 40 years and was an electronic engineer involving RF. I have been a ham close to 40 years and also know a bit about the types of coax. He just does not want to use the rg-6 types. As we both have many ot the connectors for rg-8 and adaptors for the 8x and 58 types it is no use to get the rg-6./ Also as pointed out you often need special connectors or tools to install the F connectors for outside use. He has a small setup of just two or 3 antennas and does not want to buy special tools for the rg-6. I have often use over 1000 watts for the low bands and also work weak signals on 6 meters and above. That leaves me out for the smaller coax also. Neither of us like the solid small wires for outside use on 80 meter dipoles. Too much flexing in the wind. I am not sure what the losses would be for the copper coated steel often used in some of the rg-6 at frequencies below 10 mhz where he wants to use it.

It just seems that some things seem to be in short supply at differant times in this country. Around 1974 there was a gas shortage (I think that was when the shortages started), one year it was a toilet paper shortage, one year it was a chicken shortage. For about the last year or two it was an

ammunition shortage for guns.

Every time it snows in the South US there is a big run on bread and milk and that runs out .

We were just wondering if the one big supplier close by was the only one having trouble getting coax.

I don't know much about the making of coax amd other wire, but assume it is like where I work. We make polyester material that is shipped out for car tires and other things. The machines are set up for one type of material and ran for a while . When the warehouse is stocked with that, we change the machines to run another type. If the inventory is running low on one type, it may be a while before we switch over to run it again.

Maybe the quantities of coax being manufactured these days is being
affected by the increasing demand for optical fibre?

Could be. While I would think it would take a differnat plant to make the
OF, maybe not as much coax is used and some plants have shut down making the
coax. Hard telling how many miles of coax was made for cable TV/internet
and computer connections that are now going to the OF.

unfortunately you have to learn modern em to know what writings of
maxwell and heaveside to bother believing... they both went through
learning periods before they came to the final transverse wave
formulations. if you read their earlier works you will be mislead
because they were still learning and following dead end paths like
aether theory and fluid analogies.

I think you are misunderstanding, possibly because I am not expressing
as clearly as could be. I find it difficult to pick a vocabulary that
will not be confusing due to prior associations with the words. But
then words like 'entity' are too fuzzy.

The system I have in mind has ports through which energy can flow in
or out of the system and components inside the system which can
store energy. For such a system, the energy flowing in to ports
of the system minus the energy flowing out of ports must
equal the increase in energy being stored in the system.

This must be true at all times, or energy is being created or
destroyed; a bit of a no-no.

This system can be subdivided in to sub-systems for which this
energy flow balance must also hold.

As such, if the energy stored in one of the entities (e.g.
capacitor) is increasing, either net energy is flowing in to
the ports of the system, or the energy stored in some other
entity in the system is decreasing (or both). But the sum
of all the flows entering or leaving the ports, plus
the flows between the internal entities must balance on
a moment by moment basis.

Of course the expressions written to describe this will
be dependent on the details of the system. One must also
not forget to account for energy that leaves the system
as heat courtesy resistors. These can be thought of as
ports which only remove energy from the system.

The requirement for moment-by-moment balance is more stringent
than the requirement for average balance. The former inevitably
leads to the latter, but the converse is not true.

From Wikipedia, I have just learned that the concept I am attempting
to describe is known as a "Continuity equation".

What was my argument that fell apart? I am not the one pushing the
notion
of forward and reflected EM waves. That's you. I am just trying to
help
you fit square waves in to your model.

So how do you characterize a slow square wave? Say one that is 0V for
one year, then 10V for a year, then 0, then...

With several meters of open circuited transmission line, what do you
think is happening on the line for the year while you are waiting for
the
signal to drop back to zero volts? Does it have a constant voltage?
And
0 current for most of that year? Is it an EM wave?

A question for your model...

With an infinitely long transmission line excited by a step function,
is there an EM wave propagating down the line?

If not, what is it that is propagating down the line? Especially at
the leading edge?

> is 0hz

You have used similar phrases before. Are you suggesting that an
open circuited transmission line excited with a step function takes
infinitely long to read steady state?

Hello all, friends.

Sorry, I thought we was basically alone in this issue with Richard :>)

Then, perhaps some of you can help me if I am not capable to make my poor english writings intelligible enough. I feel as if Richard had not pointed in the direction I point. I think that because his references to S+N/N and others made me think Richard are thinking in detect low frequency wave quanta at little energy levels, and I am talking about to perceive the little LF quanta at high energy levels (large scale oscillators).
In my original example I said we are not able distinguish (today... tomorrow who knows?) Osc. A from Osc. B, having Osc. A 4*10^28 quanta and Osc. B 4*10^28 +1 quanta, having each 80 m quantum 2.3 * 10^-19 J.

(I know my friend Richard inevitably is going to penalize me for this "analogy", but it is so beautiful that I could not resist..!) => The problem is such as distinguish between two zeppelins of about 1500 m^3 each one having zeppelin A only one molecule more than zeppelin B...! Do not we need an alien Roswell Grey technology for that? :>)

Last night I found in the web the "strange word", it is not "granularity" it is => "graininess", graininess translate to spanish properly to "granularidad" and granularidad to english as granularity :>)

At the end of this link:
http://panda.unm.edu/Courses/Finley/P262/ThermalRad/ThermalRad.html there are a similar text in its original english words =>

"Therefore, we see that the quantization of energy simply does not show up for large-scale oscillators. The smallness of Planck's constant makes the graininess in the energy much too fine to detect in those experiments. This is quite similar to the statement that we do not ordinarily observe the fact that the air in the room is actually made up of many, many individual molecules. Nonetheless, we can indeed perform experiments in which this graininess is noticeable, and even important. Obviously the behavior of the spectral radiancy at very short wavelengths is one such case. The phenomena involved with the photoelectric effect, and the Compton effect, are others."

I apologize for my insistence dear Richard, I do not want to be stubborn but I remember Carl Sagan telling: "Extraordinary claims require extraordinary evidence" and my posting about the very large quantum number of the 3.5 MHz Xmtrs play here the "conservative" role :>)

73 to all Miguel - LU6ETJ

PS: Szczepan: Thanks for your info.
Richard: Why a "white board"? has a special meaning? - You are saying Cecil it is as Dr. House? - Really nice car your RX-7, I envy you! - My London friend is "missing2 I owe you some answers :>(

One example you should be familiar with is Kirchoffs Current Law;
it tells you that sum of the FLOWs must equal 0 based on the
Conservation of Charge law. Recall that current is charge per
unit time.

For a more general treatment look up 'Continuity equation' in
Wikidedia where you will find "A continuity equation in physics is a
differential equation that describes the transport of some kind of
conserved quantity. Since mass, energy, momentum, electric charge
and other natural quantities are conserved, a vast variety of
physics may be described with continuity equations.".

Welcome to a new tool for analysis.

See above, though it seems the common term is Continuity equation.

Inside the box are some elements whose stored energy is increasing
at the same rate.

> > Instead, think that at every instant, the energy flow between the
> > entities in the experiment must balance.
>
> You are contradicting yourself. Assume the capacitor *IS* the system

Expand your thinking a bit. Energy is being stored in the capacitor.
You do need to account for this. It is just another flow to track.

Under the assumption that even though my topic involves an LNB, and
that's not technically a radio, I'll beg your pardon for pressing on
under the guise of "radio" astronomy. Maybe someone here talks LNBs and
satellite signal devices.

I constructed the battery pack in the link above, but w/o the coil. I
plugged it into the 1004ifd and immediately got something of a single
note noise from the device. This seems wrong. Any ideas? I did not
connect to the LNB and disk.

learning periods before they came to the final transverse wave
formulations. if you read their earlier works you will be mislead
because they were still learning and following dead end paths like
aether theory and fluid analogies.

Maxwell's aether was as perfect solid with the molecular vortices. The
magnetic field was the sum of the molecular.
The Faraday effect was explained. Transverse waves possible. But in solid
possible are also the longitudinal.
Which of them are in reality decide experiments.

Heaviside modified Maxwell' model. His aether is also motionless but withot
the molecular vortices:
http://en.wikisource.org/wiki/Electromagnetic_effects_of_a_moving_charge

Now inside the solenoid no rotations. What rotate the polarisation plane?

Heaviside (father of Maxwell' equations) did not understand Maxwell and did
not agree with the rest:

"Prof. Thomson, who otherwise confirms my results, has also extended the
matter by supposing that the medium itself is set in motion, as well as the
electrification. This is somewhat beyond me. I do not yet know certainly
that the ether can move, or its laws of motion if it can. Fresnel thought
the earth could move through the ether without disturbing it; Stokes, that
it carried the ether along with it, by giving irrotational motion to it."

" I must, however, disagree with Prof. Thomson's assumption that the motion
must be irrotational. It would appear, by the above, that this limitation is
unnecessary."

I simply agree with Maxwell, Stokes, Thompson and the rest famous scientists
that no rotational vibrations (transverse waves).

You prefer Heaviside (engineer) and Authors of the textbooks .

Hi Miguel,

Sagan never impressed me, and this quote even less. It relies on
mystical explanations when ordinary works quite well.

>and my posting about the very large
>quantum number of the 3.5 MHz Xmtrs play here the "conservative"
>role :>)

The link leads to a lot of tedious and pedantic writing.

Your new analogy fails as quickly as the rest, so by extension I must
presume that the work revealed at your link fails too. That is the
usual fate of tying two things together when one is a rhetorical
anchor.

When I speak of S+N/N, this is to mean that extraneous detail (fables
of mosquitoes, large cars and even larger blimps) only adds noise.

Skip the "extraordinary," stop the fables, and simply state your case.
When you remove all this noise, you may discover you are not writing
about a quantum system at all, but numbers without meaning. A simple
test: what changes its quantum state at 3.5MHz? Is it sub-atomic,
atomic, or molecular?

>Richard: Why a "white board"? has a special meaning? - You are
>saying Cecil it is as Dr. House? - Really nice car your RX-7, I envy
>you! - My London friend is "missing2 I owe you some answers :>(

Dr. House refuses to let students write on his white board.

I've driven RXs for 28 years: a 1978 and a 1990 GTU.

London is a nice place to be missing in. I've spent time near
Vauxhall bridge in Westminster.

'it depends'... in the special case you have concocted where the signal source has no reflections it only takes one round trip. this case is very misleading if you try to extend it to cover other cases. in general it takes infinitely long and you must account for the infinite series of reflections. that is why the approximations used to come up with the sinusoidal steady state solution is so useful, and exactly why it can not be applied to steps and square waves and other non sinusoidal constant sources.

and in your infinite line example it never reaches steady state so the step wave propagates forever.

'normally' black boxes are just that, opaque elements that you can not measure an internal state with. when you specify a box or something generic with a couple of ports any good engineer will assume that you know NOTHING about what is inside the box, and that you don't care. those type of simplifications are common in engineering methods in order to simplify problems down to the things that you are really interested in... normally BY DEFINITION you don't know and don't care about what is inside 'the box'. so your statement that you know the energy stored in the box is a function of instantaneous flows in and out is non-sequitar, we engineers just don't care and would never try to do a balance like that. if you want to study the energy flow in and out of a box AND the storage of it in the box then provide the circuit for the box and study it properly.

for instance, take your infinitely long transmission line. as an engineer my first action is to reduce that line to a resistor that has a value equal to the characteristic impedance of the line. i can use that equivalent resistor for all calculations for EVERYTHING ELSE in

the circuit, but NOT for the internal state of the replacement box....
for obviously if you look in the box and find a resistor dissipating
all the power you put into it as heat that will be much different from
looking in the box and seeing an infinite transmission line with all
that energy propagating forever as an em wave.

if that is all the further you have read then you have much to learn.
at the very beginning they are conjecturing about the possibility of
infinite vs finite propagation velocity, so obviously they have not
made the critical measurements yet to refine the equations to the
proper ones and eliminate all the possible aetheric solutions.

> destroyed; a bit of a no-no.

But you are not tracking energy - you are tracking power. As Roy has said, there is no requirement that instantaneous power must balance. Where are the stored energy terms in any of your instantaneous power equations? How do you handle the difference in dimensions between energy and power? The only condition for which NET power must balance is during a time interval in which there is zero NET stored power, e.g. during one cycle.

I have rev'ed my zero interference article to include the following statement:

"Over a time period of many cycles, e.g. one second at MHz frequencies, the net average energy and the net average power are related by joules/second. Thus, if certain conditions are met, net average power can be used to track the net average energy flow based on the conservation of energy principle. However, at time intervals of less than one cycle, as exists for instantaneous power, power cannot be used to track energy because energy is often stored in a reactance, is not moving at that instant, and is therefore technically not power. In fact, unlike energy, power often appears and disappears. There are special cases where average power in joules/second can be used to track average energy in joules but instantaneous power is not one of those special cases."

> From Wikipedia, I have just learned that the concept I am
> attempting to describe is known as a "Continuity equation".

In all your previous equations, you have presented only the first term and completely ignored the second (delta-dot-v) term of the equation which is required for balance. When you add the proper term, i.e. you track and account for all of the energy, your energy equation will balance - as I told you days ago.

> So how do you characterize a slow square wave? Say one that is 0V for
> one year, then 10V for a year, then 0, then...

The same way I characterize, "How many angels can dance on the head of a pin?" The length of time makes absolutely no difference to the concept involved. The above conditions do not match the DC steady-state conditions of your earlier example.

> With an infinitely long transmission line excited by a step function,
> is there an EM wave propagating down the line?

Yes, there is an EM wave at the leading edge. Electrons cannot move at the speed of light. But it is impossible to window such an example in a valid manner because windowing creates other EM waves where none exist in your example. There is no trailing edge in your example yet windowing would necessarily create a trailing edge. Since an infinitely long transmission line is impossible, we are back to the "angels on the head of a pin" problem. In any region of the example where steady-state DC conditions exist, EM waves have ceased to exist. That's what happens when you make the line a fixed length and terminate it at that point. Anywhere DC steady-state conditions exist, your DC forward and reflected wave analysis falls apart.

Your infinitely long open-circuited transmission line example
certainly takes infinitely long to reach steady-state so the leading-
edge EM wave continues forever with zero reflected EM waves and your
argument involving reflected waves falls apart.

Your finite open-circuited transmission line example reaches DC steady-
state where EM waves cease to exist so your argument involving forward
and reflected waves falls apart.

> Expand your thinking a bit. Energy is being stored in the capacitor.
> You do need to account for this. It is just another flow to track.

I don't need to track it. I am not the one who is arguing that
instantaneous power is conserved. I have said all along that your
instantaneous power equations were not tracking all the energy. It is
you who have not been tracking the energy stored in the capacitor.
When you do that in a valid way, you will discover that the energy
does balance but the instantaneous power still does NOT balance, nor
is it required to balance. IT IS ENERGY THAT IS CONSERVED, NOT POWER!
Please note that the 'Continuity equation' discussion does *NOT* list
power as one of the conserved quantities.

at the very beginning they
infinite vs finite propagation velocity, so obviously they have not
made the critical measurements yet to refine the equations to the
proper ones and eliminate all the possible aetheric solutions.

You probably have heard about the sulimation of matter and photoemission of
electrons,
It means that in the space is the saturated vapour (todays plasma). It is
the medium for your radio waves.
It is known from Ludwig Lorenz.

Todays authors are conjecturing about the possibility of the transverse
waves. Is it not funny?
What waves are in your transmissing line?

i still want to see how you polarize longitudinal waves.

They are photonic waves, obviously subject to the laws of physics that
govern photons.

Richard has learn me that the dipoles are polarized not waves.
Monopoles do not need the directional orientation.
Directional patterns are the result of interference.

Is is trouble with understanding that the all scientists work on plasma?
Only students are in the solid aether. But they simply do not know that the
famous equations describes such.
Vectors describes the motions of something. Students should not be told what
it is. Because the goal is math (field method) teaching.

Hi Richard, good day:

Again you give me another rethoric answer... Please, tell us how to measure to distinguish Osc. A from Osc. B, having Osc. A 4*10^28 quanta and Osc. B 4*10^28 +1 quanta, having each 80 m quantum 2.3 * 10^-19 J.

Your answers are making me remember => "It was the only explicit answer you will ever get" or "Superman's cataracts with his xray vision. This is probably going to be your only direct answer." (Please do not go upsetting, I am joking).

You dislike my examples, you dislike R & H & K classic and obviously really good peer reviewed book reference (and examples), you dislike university notes, you dislike analogies, you dislike Sagan... Today I know all things you dislike, what I do not know is how measure A and B oscillator to distinguish each other... :>D
Remember, you are rebutting things stated in standard university physics book, does not reverse the burden of proof.
Please be a good boy, be plain and do not resort to old tricks such as posting esoteric rocket science hiper-specialized incomprehensible answers :>)

The problem I had was the use of "energy flow balance" which implied equal energy flow into and out of any point at any time. Your more detailed description explicitly includes stored and dissipated energy, which as we've both said, makes it possible for energy flow into and out of a point to be unequal at times, while obeying conservation of energy by being equal on the average (when dissipated energy is accounted for as removed from the system). The more detailed detailed description should help alleviate misunderstandings some readers might have had.

I can't recall ever having come across that term, but then I'm not a physicist.

SRI, I ommited to say the example of the University of New Mexico link it is similar to the one given in "Physics for scientists and engineers" (Serway & Beichner, my copy is in spanish). They say the same about it.

Humoroues note: Richard Feynman do not share your dislike for analogies he compare corks in water with charged objects fields :>)

its too hot for this, i'm going for a swim... maybe some nice
longitudinal waves in the water will make me feel better.

Of course. But this illustrates one of the benefits of "appropriately
selecting" examples. One can choose examples that do not take forever
to settle and therefore can be analyzed in finite time.

> that is why the approximations

To which approximations do you refer?

> used
> to come up with the sinusoidal steady state solution is so useful, and

Are you suggesting that it is inappropriate to use the reflection
coefficient computed at an impedance discontinuity to predict the
behaviour of a transmission line excited with a 'step, square wave or
other non sinusoidal constant sources"?

> and in your infinite line example it never reaches steady state so the
> step wave propagates forever

So is this 'step wave' an EM wave, according to your definition of an
EM wave? If not, what would you call it?

Well, it was Cecil's question and I answered it in the context of the limited information that he provided.

But I agree, we would learn much more if the experiment included some internals of the box.

Yes, indeed. Though black boxes still have their uses as an aid to learning. Or to simplify analysis when some aspect is simply not of concern.

Well, you are digging your hole deeper and deeper. You really should
take a pause and try to understand the significance of "Continuity
equations". Do seriously consider Kerchoff's current law as an
example.

Sorry, I posted my answer in another branch of the thread (I hope not to have bothered our friends...)

Hi Richard, good day:

Again you give me another rethoric answer... Please, tell us how to measure to distinguish Osc. A from Osc. B, having Osc. A 4*10^28 quanta and Osc. B 4*10^28 +1 quanta, having each 80 m quantum 2.3 * 10^-19 J.

Your answers are making me remember => "It was the only explicit answer you will ever get" or "Superman's cataracts with his xray vision. This is probably going to be your only direct answer." (Please do not go upsetting, I am joking).

You dislike my examples, you dislike R & H & K classic and obviously really good peer reviewed book reference (and examples), you dislike university notes, you dislike analogies, you dislike Sagan... Today I know all things you dislike, what I do not know is how measure A and B
oscillator to distinguish each other... :>D
Remember, you are rebutting things stated in standard university physics book, does not reverse the burden of proof.
Please be a good boy, be plain and do not resort to old tricks such as
posting esoteric rocket science hiper-specialized incomprehensible answers :>)
.....
I ommited to say the example of the University of New Mexico link it is similar to the one given in "Physics for scientists and engineers" (Serway & Beichner, my copy is in spanish). They say the same about it.

Humorous note: Richard Feynman do not share your dislike for analogies he compare corks in water with charged objects fields :>)

So you now are in agreement that flows must balance if charge (or
energy)
is to be conserved. Excellent.

For greater certainty, I paraphrase: "Only the leading edge has an EM
wave".

What is follows just after the leading edge since it is not an EM
wave?
What is it? What do you call it?

Now back to the square wave with a two year period...

After the rising edge goes by, which I assume you will still call an
EM wave, what follows until the falling edge occurs a year later?
Is it an EM wave?

If so, how is it different than what follows the rising edge of the
step wave? They both look like DC for a year.

If not, why is it not an EM wave?

No reflections here, so little impact on any argument.

When, exactly, does the EM wave cease to exist?
Just after the edge passes? Or only when the edge makes it all the way
back to the source?

> power as one of the conserved quantities.

Do study Kirchoff's current law and its relation to conservation of
charge.
Recall that current is charge per time.

Map this to conservation of energy...
Current is to power as charge is to energy.

The relationship and utility is the same.

Or you could do mass flow in a pipe junction; mass must be conserved.
Mass flow is to power(energy flow) as mass is to energy.

Or, pick any number of conservation laws to use as examples.

But back to Kirchoff...

I am sure you have made extensive use of Kirchoff's current law and
will
find "Keith's" power law equally useful, once you understand how it
works.

They are quite analogous.

...Keith

PS: Since the power law is apparently unnamed, and this is holding you
back, I make the somewhat presumptuous suggestion of naming it after
myself. But if you would prefer to call it Cecil's law, that would
work for me, as long as it has a name and you no longer feel that it
can not exist because it is unnamed.

So you finally admit I was right all along, adopt my original position, and claim it was yours all the while. Old trick - won't work. I studied similar equations half a century ago when I studied the conservation of energy principle. I told you long ago that your P(t) = V(t)*I(t) equation did not contain all the energy in the system.

I have never posted anything that disagrees with the continuity equations. You are the one who chose to ignore the delta-dot-v terms and have reversed your original position by introducing the continuity equation. All you had in your equation previously was the de/dt term.

Do you still believe in the conservation of instantaneous power principle?

No, you remain confused and mistaken. Energy flows (de/dt) do NOT have to balance. That's what I have been saying all along. Energy must balance whether it is flowing and/or not flowing. I told you weeks ago that the sum of your instantaneous energy flows do NOT include all the energy, i.e. there is no such thing as conservation of instantaneous power (energy flow). If you don't correct that basic misconception, you will never get it.

The continuity equation aids my side of the argument, not yours. It proves that you have been wrong all along when you did not include all the energy in your instantaneous power equation.

Back to the LC oscillator. At the instant when all of the energy is stored in the capacitor, energy flow has been completely destroyed, i.e. de/dt=0, yet there is plenty of energy in the capacitor. Your P(t)=V(t)*I(t) =0 equation completely ignores the energy in the capacitor when I(t)=0 and I have told you all this many times before. The continuity equation only highlights your error of ignoring the stored energy.

> After the rising edge goes by, which I assume you will still call an
> EM wave, what follows until the falling edge occurs a year later?
> Is it an EM wave?

If electrons (carriers) are not being accelerated and/or decelerated, i.e. if DC steady-state exists, then there are no EM waves.

I detect evasion. Is there a problem providing an answer?

Is what follows the rising edge an EM wave? Or not?

I invite you to view the 15.84e-9 Hz square wave as one year at
a constant value of voltage and current followed by another year
with zero voltage and current, repeated.

Or you can perform the fourier transform and obtain an infinite
number of odd harmonics of the 15.84 nanoHz fundamental.

Does either one of these views assist you with deciding whether
there are EM waves present during the one year intervals where
the signal value does not change?

If the square wave frequency was 1 MHz, would you have the same
difficulty deciding? Why not?

More evasion. So are now saying there may indeed be an EM wave present with DC? Even with DC, the electrons are not moving with constant velocity but hop from atom to atom. Seems like acceleration and deceleration to me.

Maybe you should just start with Kirchoff's current law and understand
what it says before following my suggestion to compare it with the
conservation of energy law.

You seem to have forgotten what you almost certainly once knew.

Google will provide many adequate explanations.

Not EM but the electric wave.
In the free electron laser (halbach array) is DC and waves are produced.

>Even with DC, the electrons are not moving with
constant velocity but hop from atom to atom. Seems like

2975. AIM4170 antenna analyzer presentations at the RSGB 2010 Convention

Newsgroup: rec.radio.amateur.antenna
Date: 2010-07-06 13:48:52 UTC
From: Ian Wade G3NRW <g3nrw@yahoo.co.uk>
Message-ID: <ANOPBXDERzMMFw6j@ntlworld.com>
Source record: 8475

If you are in the UK in October, you may be interested in coming along
to the RSGB 2010 Convention:
http://www.rsgb.org/rsgbconvention/index.php

The full program for the convention is here:
http://www.rsgb.org/rsgbconvention/events_programme.php

On the Sunday morning (10 October) I will be giving a couple of
presentations on the AIM4170. The first will cover the basics of antenna
measurement and the 4170, and the second will illustrate the use of the
4170 as a design tool.

Live demonstrations of the 4170 will be the main feature of the
presentations, and will include tuning a 4m groundplane, trap tuning,
designing a 160/80m trap dipole, measuring quartz crystal parameters,
using the Smith chart, quarter-wave stub tuning and measuring the
impedance at the antenna feedpoint. The final demonstration will show
how to control the analyzer remotely via a WiFi link, allowing you to
tune your antenna while standing in the yard (or on the roof or at the
top of the tower).

The presentations will be based on the material at :
http://homepage.ntlworld.com/wadei/aim4170.htm

The venue for the Convention is Horwood House in the county of
Buckinghamshire:
http://www.rsgb.org/news/article.php?id=0027

Horwood House is located about 50 miles (80km) north-west of London,
close to the city of Milton Keynes.

A further local attraction, just 5 miles (8km) from Horwood House, is
Bletchley Park, home of the World War II Codes and Ciphers School where
the Enigma and other encryption systems were broken:
http://en.wikipedia.org/wiki/Bletchley_Park

If you plan to come along to my presentations at the Convention, please
let me know and I will reserve a front seat for you!

> Is there a problem providing an answer?

I don't know how to measure the exact answer. How many photons does it take to cause a measurable EM field at one cycle per two years? If the EM field is too low to measure, how do you know it is there at all? Blind faith in a math model?

> Does either one of these views assist you with deciding whether
> there are EM waves present during the one year intervals where
> the signal value does not change?

No they don't. The problem is random/natural/man-made EM noise. When the EM wave level drops far below the EM noise, how can you measure the EM wave level? If you cannot measure it, you are back to angels on the head of a pin.

> If the square wave frequency was 1 MHz, would you have the same
> difficulty deciding? Why not?

Because I could measure those EM waves.

> So are now saying there may indeed be an EM wave
> present with DC? Even with DC, the electrons are not moving with
> constant velocity but hop from atom to atom. Seems like
> acceleration and deceleration to me.

No, EM waves do not exist at DC steady-state. Those are free electrons which do not change orbital levels. The only force acting on an electron during DC steady-state is a constant force.

> Maybe you should just start with Kirchoff's current law and
> understand what it says before following my suggestion to
> compare it with the conservation of energy law.

You have two phasor currents flowing into a junction. One current is one amp at zero degrees. The other is one amp at 180 degrees. What is the total current flowing out of the junction? Hint: There is no such thing as a conservation of current principle. If the quantity can be completely destroyed to zero at any time, it cannot be conserved.

> You seem to have forgotten what you almost certainly once
> knew.

And you seem to have invented an impossible metaphysics. So do you really know how many angels can dance on the head of a pin?

I'm afraid "periodically deflected" violates the definition of steady-
state.

I>'m afraid "periodically deflected" violates the definition of steady-
state.

In AC coulombs/s in one direction is not const In the DC is.
In this sense in the free electronn laser is DC.

I gave you that solution: multiply them. Very simple exercise
available to anyone with sufficient bench equipment. Skip the quotes
of undergraduate scribblers with little imagination that shrug their
shoulders at their own failure.

>Humorous note: Richard Feynman do not share your dislike for
>analogies he compare corks in water with charged objects fields :>)

Feynman was a humorous fellow, but you are using undergrad texts
instead of his - why?

As I've already offered, drop all the frills and adornment and tell me
what scale the source of your 80M problem exists at:
1. Subatomic,
2. Atomic,
3. Molecular.

Hello Richard, good day.

Thank you very much for your friendly company, I enjoyed this
conversation but I think it is time to go back because it is leaning
dangerously close to an eristic exercise :>)
I am sure we will have very interesting other things to talk about our
common topic.

Best regards

Your friend Miguel

correct, the 'step wave' is not AN EM wave, it is an infinite
summation of EM waves.

DC does not an EM wave make... nor does one year make DC, the
summation is infinite, you must wait FOREVER for DC to be achieved and
by then you just won't care any more.

beware cecil... remember, there are electric fields, and there are magnetic fields, there is NOT an Electro-Magnetic 'Field'! there are Electro-Magnetic WAVES but NOT a 'Field'! he is trying to draw you in! remember DC is forever, any direct current creates a Magnetic FIELD... and any net charge imbalance would create an Electric FIELD (though DC does not require a charge imbalance, only a moving charge at a constant velocity). But in any case if it is a stream of charged particles moving at constant velocity forever they create an Electric FIELD... BUT there is no Electro-Magnetic WAVE produced by those static fields.

note, if you google 'electromagnetic field' you will indeed find may misuses of the term, including wikipedia that inappropriately abreviates it EMF, which we all know means Electro-Motive Force. The term 'electromagnetic fields', little f, and plural, is commonly used to refer to collections of electric and magnetic fields. This is seen quite often when talking about relativistic transformations where the electric and magnetic fields are linked by the frame transformation.

Excellent attempt at diversion.

> If the

Plenty of joules are being moved per second. There is no reason to
expect the field to be small.

The signal is well above the noise.

What if the signal was a sinusoid instead of square wave?

Is it then 'obviously' an EM wave?

> > If the square wave frequency was 1 MHz, would you have the same

Same joules per second. Lots of energy to detect. My 'diversion'
detector is still firing.

I suppose that is an obtuse hint that you understand Kirchoff's
current law, but why not just come out and say it.

Assuming that you have grasped it, study how it is derived from
and relates to the 'conservation of charge' law. Remember that
current is the rate of flow of charge.

Then contrast those two laws with the previously discussed
power (rate of flow of energy) and 'conservation of energy'
law.

You should be able to discern the similarities.

...Keith

Well at least there is no attempt at diversion here.

What is the shape of these EM waves of which there is an infinite
number which sum to a step?

But previously you said the line would settle after one round trip if
the source was matched. How is this consistent with having to wait
forever?

Hello friends:

A few years ago I posted in this newsgroup a doubt from a friend of me about DC current (such a batery connected to a lamp) radiating EM waves... It was in topic "Antenna gain question" (2005-10-31). My answer wold be that classic physics postulate EM radiation from accelerated charges in closed circuit because charges are under centripetal acceleration (I though of ciclotron radiation analogy, of course). My friend Richard Clarke disagreed with my hypothesis and I archived the issue for a couple of years, (he give me some analogies with moving cars, I remember...)

Time later I was casually reading some pages from Kraus and I found the answer! :>D: Kraus says: "a charge moving at uniform velocity along a curved or bent wire it is accelerated and radiates".

The clue was in words "straight wire" , he says: "Electric charge moving with uniform velocity along a straight wire does not radiate". then, a DC also must be rectlinear (perhaps it must move on a geodesic, but I do not know general relativity enough to say it) (*)

Of course, the similarities are so obvious I don't even need to state
them. Why are they not obvious to you?

There is a principle of conservation of energy. There is no principle
of conservation of energy flow (power). All you have to do to destroy
power is stop the flow of energy. All you have to do to create power
is to start the flow of energy.

There is a principle of conservation of charge. There is no principle
of conservation of charge flow (current). All you have to do to
destroy current is stop the flow of charges. All you have to do to
create current is to start the flow of charges.

Posting-Frequency: posted monthly
URL: http://www.faqs.org/faqs/radio/personal-intro/

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been
recently revived by an active moderation team. We are currently seeking
suitable information, FAQ, and bulletin articles from the entire
rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our
newsgroup.

We are seeking a replacement maintainer for the following information
bulletin formerly posted to rec.radio.amateur.* (and currently archived
at http://www.faqs.org/faqs/radio/personal-intro/ ):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

One significant omission, requiring immediate updates, for this article |
is that it does not mention newer amateur radio newsgroups created since |
it was written, including: |

rec.radio.amateur.antenna |
rec.radio.amateur.boatanchors |
rec.radio.amateur.dx |
rec.radio.amateur.equipment |
rec.radio.amateur.homebrew |
rec.radio.amateur.moderated |
rec.radio.amateur.space |

We are willing to provide any technical support necessary to get this
article updated and automatically posted again at a regular interval.
This would include establishing contact with the original maintainer for
any necessary permissions. We would prefer to seek a new, dedicated
maintainer at this time, rather than start auto-posting the original
article ourselves.

For more information about our newsgroup, see:

> create current is to start the flow of charges.

and partially contrasted the two. But you did not show how Kirchoff's
current law derives from conservation of charge.

Still, you have made some progress, so I will try again with showing
the derivation, though this time with charge and current.

Conservation of charge requires that:
the charge added to a region
- the charge removed from a region
equals
the charge originally in the region
+ the increase of charge stored in the region

When the charge can be described with functions of time, we can write:

Qin(t) - Qout(t) = Qoriginal + Qstored(t)

Differentiating we obtain

Qin(t)/dt - Qout(t)/dt = 0 + Qstored(t)/dt

At a junction, where charge can not be stored, this reduces to

Qin(t)/dt - Qout(t)/dt = 0

Alternatively

Qin(t)/dt = Qout(t)/dt

Recognizing that Q(t)/dt is charge flow per unit time or current we obtain Kirchoff's current law, colloquially: the current flowing in to a junction equals the current flowing out of a junction.

I leave it to you to do the similar derivation for energy, based on conservation of energy. The result will be

EnergyIn(t)/dt = EnergyOut(t)/dt

And similar to Kirchoff, this applies at a juncion, a place where energy can not be stored.

Of course Energy(t)/dt is just a mathematical expression of energy flow or power, so we obtain

PowerIn(t) = PowerOut(t) (at a junction)

But don't beleive me. Do the derivation yourself. You can pattern your derivation on the one above for Kirchoff.

I'd go on to show how my analysis of your circuit carefully picked junctions that could not store energy, but I have found it better to educate one step at a time. So we can do that later.

...Keith

T'is when the thing you claim not to know has nothing to do with
the problem at hand.

As i pointed out, the energy levels are well above the noise.

And you skipped the intriguing question...

If the signal was a 50 W sinusoid at 15 nHz, would you have the
same reluctance to declare it an EM wave? It is a sinusoid.
What criteria could it possibly fail to satisfy?

At what frequency would you no longer be reluctanct?
1 microHz
1 mHz
0.1 Hz
1 Hz
10 Hz
100 Hz
1 kHz
10 kHz
?

Real applications run at 10 kHz so I assume you would accept,
without concern, at least this number. Where would your
trepidation begin?

> As i pointed out, the energy levels are well above the noise.

You have certainly not proved that to be true. The current is essentially DC for most of the year. Therefore, you cannot assume the proof to the question of whether the photons, which may or may not exist, are above the noise level. (Hint: assuming the proof is one of the most well known logical diversions.)

What I said was that one photon at 0.5 cycles/year is NOT above the noise. You are free to try to prove that I was wrong. If you window your signal for 1/2 of a year, I believe you will find it to be DC steady-state. I do not believe it is far enough removed from DC to generate any detectable photons.

I will be away from my computer for a few days. In the meanwhile, I suggest that you prove that a conservation of power principle exists and a conservation of current principle exists. Until you do that, you are just blowing smoke. But it you succeed, you will no doubt receive a Nobel Prize.

Over the years I have seen many patterns for horizontal dipoles and the inverted V antennas,but do not recall seeing any V shaped patterns in the books. That is a dipole that is supported on the ends, but sag in the middle. I know the sag is needed to some extent because of the weight of the wire and feedline, but what happens to the pattern if it is say 1/2 wavelength or 1/4 wavelengths at the ends and the sag in the middle is changed. Maybe drop it a few feet, then 10, 15 and 20 feet for 80 meters.

I know that for maximum distance you usually want the high current portions up high,but maybe it will be better as a close in or omnidirectional antenna if the center is lowered somewhat.

In EM current is incompressible. EM is older then electrons.
"charge can be stored" apply to electrons. It is impossible to marry EM and
electrons.

>Until you can prove a conservation of current principle, you are
wasting my time.

"According to theory" a conservation of current principle (continuity
equation) is the assumption.

In EM is the displacement current in solid insulators (also in vacuum). It
is always incompressible because the motions of the particles are
synchronized (charges can not be gathered).

EM is beautiful but useles in techniques. It is useful to teach the math.

Yes, very interesting example (and device),

Cecil it is right respect a photon/noise power ratio, even one photon
of 80 m per second it is very below of noise at 1 K, 80 m-quantum/
Noise dB ratio @1 Hz BW = -38 dB.

Respect to DC current EM radiation, In that time Richard bring an
interesting example of 20 kV electron rectilinear beam rendering a
frequency of 34.6 EHz, the calculus it was quite right, but that
frequency it is not EM waves radiated by electrons but a "matter wave'
frequency... (idem with car analogy => not charged and acelerated
cars :>) do not radiates EM waves, but may have a matter wave
asociated to them).
For these reasons IMHO I think -as Cecil do-: basic (undergraduated?)
physics books are very useful to helping us to better understand and
enjoy our ham topics.

In free space, there is not much difference in pattern between a dipole that is perfectly horizontal and one that is drooped or sags (or for that matter one that is bent horizontally). What changes is the feedpoint impedance (72 ohms for perfectly flat, getting towards 50 ohms with a 120 degree included angle).

The other thing that changes is the apparent height above ground. If you model a drooped dipole and fiddle with the height to try and match the vertical pattern for a perfectly flat dipole, you find that the "effective center" of the drooped dipole is around 1/3 of the droop distance. That is, if you had a dipole where the center were at 100ft, and it drooped 30 feet on either end, the pattern is about the same as a flat dipole at 90 ft.

The height above ground has a HUGE effect on the dipole pattern (especially at low elevation angles) and probably dominates any small changes.

After all, a perfect dipole has a gain of 2.15dBi and a infinitely short dipole has a gain of 1.6dBi, and a drooped or sagging dipole pretty much has to be somewhere in between.

Those gains are for dipoles in free space. A dipole over ground
typically has several dB greater gain.

The absolutely worst gain any efficient antenna can have in free space
in its best direction is 0 dBi. So nothing you can possibly do to the
pattern can reduce it below this value in free space, as long as you
don't introduce loss. But as Jim says, you can mess with a dipole a fair
amount without changing the pattern much -- except for filling in or
moving the nulls, which can be very sensitive to small changes.

This is toooooo amusing.

You refuse to start to examine the proof because it has not yet been
proved ... which can not happen until you examine the proof.

You are truly amazing at developing mind stopping techniques that
inhibit your ability to learn.

Of course, there are many photons in the 50W signal previously
mentioned. That is the only way to get to 50W.

> are just blowing smoke. But it you succeed, you will no doubt receive
> a Nobel Prize.

Ahhm, so you are proposing a new concept: a lower frequency limit
where
a sinusoid stops being an EM wave and becomes what? Slowly varying DC?

I have never seen such a concept mentioned previously. Perhaps it will
be you who deserves the Nobel prize.

At what frequency, approximately, is this limit?

Or, if that is not yet known, what is the lowest frequency that you
are currently convinced would be an EM wave, such that the cutoff
must be less than this frequency?

Ballpark is good:
1 MHz
10 kHz
1 kHz
100 Hz

10 Hz
1 Hz
0.1 Hz
0.01 Hz
0.001 Hz
1 uHz
1 nHz

Just to the nearest order of magnitude, from the above list, which frequency are you sure is still an EM wave rather than slowly varying DC?

I am pretty sure that you would accept 10 kHz as been EM. Omega used to be around 10 kHz.
How about 60 Hz? This is standard AC power in some jurisdictions.
25 Hz used to be common as AC power.
10 Hz? Is the audio on its way to the woofer an EM wave?
1 Hz?

Just an order of magnitude frequency that you are sure your EM cutoff frequency will be below.

And how much above the noise does a photon have to be for you to consider it to be a photon? Perhaps this will help you choose your cutoff frequency, though it seems to me you will have some difficulty when there are lots and lots of photons at this low frequency. Will this not be adequate for detection?

By the way, is it possible to detect a single photon at 10 kHz, a frequency which I am pretty sure you would consider to be an EM wave.

Sure. You described charge flow in and out of an isolated node with no need to reference any other node or part of the circuit. Then you say the same thing can be defined for energy. However, how is energy defined in terms that only refer to characteristics of the node without involving any other part of the circuit or other nodes.

That has absolutely nothing to do with the quality of the persons
work. If they no longer enjoy it, and many never did from the start,
they chose the wrong field. Generally when a person becomes bored
with their work, or dissatisfied the quality of their work suffers.
With nearly 35 years of working I saw a lot of that.

If you are a professional who is bored out of their mind, quitting and
going back to college to pursue a different field certainly is an
option.

That is what I did after working over 26 years.
I originally enjoyed the work and had fun on the job. Did that make me an amateur professional? I chose the line of work because I loved doing it. OTOH there were those who figured I must not be doing my work because I appeared to be having "too much fun". After changing professions and jobs I ended up working for and with people who were not so narrow minded and understood. When I retired it was as a project manager with good people working for me and good bosses above me.

I still loved the work, but I had reached the point where I was seeing too many people working until they dropped at work, or retiring and dropping within a month or two. OTOH I saw more than a few who didn't know any thing other than work. I decided I wanted to go play.

I also love retirement (does that make me an amateur retiree?) , but it could pay better.

That is why we have "project Charters" The "Charter" describes the
project goals and how to determine when those goals have been met.

Any change in goals, or how to determine they have been met means
going back and rewriting the charter and then having all involved
reauthorized it.

My standard replay when some one asked if we could do something with a
project was "is it in the charter?". If not they had the option of
getting the heads of all the involved departments and often "sites" to
review the project charger. That usually minimized attempts to expand
projects beyond their original design. It also give all involved the
desire to put everything on the table at the beginning. <:-))

I really don't see it in that light. To me there is no higher rank
than amateur. A professional can just be a "grunt", or they can be
some one with goals, or rather "goal oriented".

>Yes, very interesting example (and device),

>Respect to DC current EM radiation, In that time Richard bring an
interesting example of 20 kV electron rectilinear beam rendering a
frequency of 34.6 EHz, the calculus it was quite right, but that
frequency it is not EM waves radiated by electrons but a "matter wave'
frequency... (idem with car analogy => not charged and acelerated
cars :>) do not radiates EM waves, but may have a matter wave
asociated to them).

Each waves are the matter waves. The speed is the particles mass dependent.
So in the wire the sound waves travel with the low speed (medium are ions),
and the electric waves (medium are the free electrons) with the extremally
high speed.

>For these reasons IMHO I think -as Cecil do-: basic (undergraduated?)
physics books are very useful to helping us to better understand and
enjoy our ham topics.

For graduated is the field math only.

>or would it be better to remove the screws so the traps can
>be adjusted with the drain holes down?

I've used a TH-5 for quite a few years. The drain holes should be
down, but if they are no more than 20 degrees off if the disassembly
is difficult as it sounds, I'd simply drill additional drain holes
that would point straight down. The two sets of holes would probably
drain better any way instead of the meniscus stopping the drainage.
Just make sure the new holes are no larger than the old ones. It does
no good to get better drainage if the critters are going to move in.
The drain hole in the matching network for my AV-640 was large enough
for a paper wasp to get in. The virtually packed it with nests. 800
watts on 6 with a KW on HF was enough to thoroughly cook the critters
and mess up the matching.
http://www.rogerhalstead.com/ham_files/AV-640/AV640.htm

The AV-640 is a good antenna. I've been working world wide using it on
40 since mid winter. It leaves a bit to be desired on 6, but I'm used
to a 7L Yagi on a 30' boom at 115'.

Perhaps some examples will help.

Consider the output terminals of a generator to be junction. Then the
power delivered from the generator to the junction must exactly equal,
at all times, the power taken from the junction by the load, since
there is no storage in the junction.

It should be noted that the 'junctions' used for a power analysis
are not the same as the junctions used in Kirchoff's current
law. The concepts are analogous, not identical.

Another example. In the simple Thevenin generator, the power provided
by the voltage source must exactly equal, at all times, the power
taken by the resistor plus the power taken by the load. In this
example, it is difficult (impossible?) to identify a physical
'junction' where the power must balance, yet the notion is still
applicable.

Jim,

My simulations, and some practical experience, has found that an
included angle closer to 90 degrees yields a 50 ohm feedpoint impedance.
These are 'practical' designs, and not in free-space, of course. Is

there a reference you can give me that derives the 120 degree 50 ohm result?

I will leave you with this parting thought. All that you are saying is that the power at one point (special case: away from any energy storage device) is the same as the power at another point in the same wire (special case: an infinitesimal distance away). No rational person would argue with you on that point. However, that is NOT a general case and in no way proves that power is conserved in general. It is simply a special case where there is a one-to-one correspondence between energy and power, something I pointed out earlier.

The throw of a switch can cause power to be created or destroyed. The throw of a switch cannot cause energy to be created or destroyed. That's the basic conceptual difference between power and energy that you are missing. The same thing is true for current vs charge.

In my energy articles, I took advantage of the special case of one-to-one correspondence between average energy and average power. You neglected to do that for your instantaneous power calculations and proved beyond any doubt that power is not conserved. Your own continuity equation posting indicated that you had erroneously omitted something important from your previous calculations.

It sounds like your "junction" for energy analysis is what's called a "port" in RF analysis. If so, it would be less confusing for you to use that term, since "junction" has a different established meaning in circuit analysis.

For some reason, Keith prefers living in the theoretical world rather
than the real world. His idea of reality is what his math model
subliminally tells him to believe. He doesn't seem to know that
reality is supposed to dictate math models, not vice-versa. :-)

P.S. Let's go card-counting.

Signalwise, a 20M hamstick on a visegrip mount has worked ok for me. But
I got way too much RFI into people's plasma and LCD TV sets.

I agree with Roger here. However, there is, for lack of a better word, a forced rigor or discipline that comes from having to make a living at something. A professional who is "making a living at it" has to meet some minimum standard, or they'll be forced to choose another activity in order to keep body and soul together.

An amateur is under no such restriction. So the "spread" in ability/quality/whatever metric is greater on the bottom tail of the distribution for amateurs.

One sees this very markedly in professions such as acting or modeling.

you might be right.

Some NEC I did a few years ago showed about 57 ohms.

http://home.earthlink.net/~w6rmk/antenna/zdipolev.htm

Since Google is my friend... I found:
J. Earl Jones (probably not the actor) had a paper in IEEE Trans on Ant and Prop (May 1976) "Analysis of the Symmetric Center-Fed V-Dipole Antenna" shows, in Figure 6, numbers like you report.. At 90 degrees, somewhere between 40 and 50 ohms, and at 120, a bit below 60 ohms (for very thin wires.. h/a = 20,000

The same graph shows that the reactance (for a fixed length) also changes, which has the practical implication that the "resonant" length for a V will be different than a flat dipole.

The paper has analytical, models, and actual data in it. He compares the model data to approximations from King.

And here you go for some more data (although this is more like a half rhombic)

The cost of Copper(World wide) hit an all time high about a year ago,
(maybe a bit more) by, IIRC more than rippling, but then dropped
substantially, although not to the original level. It has been working
its way back up slowly.

Another commodity that has skyrocketed is wood. My neighbor did a
remodeling job this spring and saw the price of plywood take a
tremendous jump. Again, this is world wide, not a local or country
wide problem.

The economies of the two most populous countries are taking off at
fantastic rates. In the next decade India will have more college
graduates entering the middle class than the entire population of the
US. China has an almost unbelievable housing boom.

Don't expect things to get much cheaper.

Hello Szczepan, good day:

I do not know if I undestood quit right your sentences (we are both
out of our native lenaguage) correct me if I am wrong.

Today we do not conceive unverse as a material thing, then if you want
to say with "each waves are material waves" that all is mater you are
talking with century XIX words/concepts.
However matter waves are not neither mater nor energy waves, they are
"probabilty waves", probability it is not a "thing", it is a
mathematical concept, surely you know that.

73 - Miguel - LU6ETJ

I prefer the term 'port' as well, but for this particular dialogue I
was
trying to emphasize the analogy between conservation of charge and
conservation of energy by continuing with the same terminology.

Unfortunately, it did not appear to help.

From now on, 'port' it is.

I'd just take some rg-58 coax, and some wire and make a dipole.
Then string it up best you can. IE: one leg could be horizontal
stretching into the building along the floor or ceiling, and the other
end could just hang loose vertical from the balcony.
It's only 16 ft a leg for 20m, so shouldn't be too hard to find a way
to
squeeze it in.
A small weight could hold the hanging end down.
Of course, if there is metal everywhere, coupling to the antenna
could be a problem, and effect tuning.

The new concepts are create every day. All must be verified by experiments.

All concepts on "inmaterial waves" was created by scientists who did not
know that in the space is matter.
Ludwig Lorenz know that because he had known what the sublimation is.
"surely you know that" also.

If you accept the matter in the space when you do not need the EM waves and
"probabilty waves".

don't worry about mr. b... he is stuck in the 19th century. some day
he may discover that some of the fun things they thought about back
then like magnetic vortices and aether were soundly debunked in the
20th century.

My initial EZNEC models of this antenna have not encouraged me to
continue.

In addition to other issues, the pattern tends to be straight up.

I will make certain that any dipoles I put up in the future will have
the center at least as high as the ends.

OTH, I will put on my DO LIST to investigate the characteristics of
turning the antenna on its side. If the pattern merits, I will
consider the matching situation.

Very interesting!

I am in plasma physics. It is in XXI century. It is nothing wrong that I
know that Ludwig Lorenz discovered space plasma in XIX century.

> some day
he may discover that some of the fun things they thought about back
then like magnetic vortices and aether were soundly debunked in the
20th century.

They were debunked in XIX century.
I do not understand why you and some others use still "magnetic vortices and
aether".
Do not you know that the Heaviside equations describe them"

That's likely because the effective height of the antenna is low. A
low antenna on 80m means cloud/worm warmer. (and low, in this context,
means <20m, which is still way up in the sky).

So the traditional single support inverted V has all sorts of advantages:
only one support needed
puts the important part of the antenna (the middle) up high

well, then the heaviside equations you are looking at are out of date and worthless... go study what is currently described as maxwell's equations instead.

They were debunked by Royal Society. Some years after that Heaviside
reworked them. Royal Society did not accept Heaviside. Now people write what
they want. Why I should go "study what is currently described" about EM.

I prefer real physics.

For many it is difficult to get an antenna up more than 60 feet. That is close to 1/4 wavelength or less. My back yard has trees on each side and it was easy to string a dipole close to 60 feet on the ends,but no way to support the antenna in the middle. That was why the question of should I string the dipole as tight as possiable with out breaking or adjust the drop in the middle to some optimum distance for what I want to do. I sort of thought the mort horizontal it is the beter the signal would be at a distance, but there may be an optimal angle to have a 200 to 300 mile antenna.

Hi Ralph,

John's suggestion of using EZNEC in its free version would easily
answer all the questions, test all the assertions, and find all the
unstated characteristics in one fell swoop. It would also let you
find the necessary attributes to obtain your goal.

EZNEC would do all this faster than the 12 blind men trying to
describe an elephant.

However, as for your several questions above. You are not going to
discover gold at the end of the rainbow by tightening the droop. In
fact, getting it to an optimal height (as has been hammered home
several times as a principle necessity) won't budge your distant
contact's S-Meter more than a couple dB (about the width of the
needle).

I'm a bit late to the party, but...

To me that seems like a lot of elements on a short boom, (I use 7L on
a 29' boom) but properly adjusted they can give more band width rather
than gain as gain is more a function of boom length. Also, how do they
get 50 ohms at the feed point of a dipole driven element in a 6L
Yagi?

Direct connect can work, but how well is another question. It may
give a good match, it may transfer the power efficiently, but again
the question is, how well does it work.

Jim Brown's (K9YC), A Ham's Guide to RFI, Ferrites, Baluns, and Audio
Interfacing ...
www.audiosystemsgroup.com/RFI-Ham.pdf is well worth reading. when it
comes to using toroids and the old "coil of coax" as a rather
inefficient current balun (which I used for years).

I worked a station down in Central America (on six) who had his new
rig on the bench testing it with a short piece of wire stuck in the
coax connector...I'm in Michigan. He could have said, that short piece
of wire on the bench was a good antenna...at that moment.

But given you get a good match, the pattern is still going to be
distorted. You can take 4 2.4" OD toroid cores with 4 or 5 turns of
coax through them to make a very good current balun (bout 5,000 ohms
isolation) and center feed a split driven element, then the antenna
is not really "direct connect" as the "matching device" is between the
feed line and antenna even though it can be the end 5 to 8' of coax
wound on the cores.

BTW, run the coax through the toroids before installing the connector

>
>
>I wonder how far above the A4 the 6 meter needs to be. I only have a
>5ft mast.

Should be and what you can get away with are often quite different. A friend has a bunch of antennas on one tower that are all way closer than they *should* be, but he gets acceptable performance, at least to him and that's all that counts. Having said that, 5' would be considered very close and 10' would be much better. OTOH you will probably be satisfied with the performance over a simple antenna. All antennas are a series of compromises as are installations. IOW we use what we have and hope for the best. You only have a 5' mast, so I assume that a taller mast is out of the question which makes "how far apart do they need to be" a moot question. Then the real question is: Will they work with only 5' of spacing? The answer is ... Probably and they probably will work fairly well.

One element to keep in mind (no pun intended) is with the antennas only 5' apart they may tend to detune one or both a bit and also lower the feed point impedance. But it's what you have and you won't know until you try.

Getting things to work is half the fun, at least it is to me...as long as getting the project to work does not run into frustration. <:-))

73 & Good Luck.

I can't tell from your comments if you think there is a problem with the phone or Consumer Reports.

From what I've heard there are repeatable problems, but I've heard no coherent explanation of what might be occurring.

The thing that seems to be consistent is that left handed users have more reported problems than right handed users.

Hi Tom,

By any account, there's a problem. Now, as the iPhone has had
demonstrable connection issues in the past, it was blamed on AT&T who
bore the brunt of that criticism.

Reports long following this past connection problem has borne out that
AT&T had adequate 3G capacity, and AT&T chose to take the bullet for
their customer (Apple, if anyone has lost track) who had a marginal
design in their protocol stack (poor through-put and high retry
traffic).

> From what I've heard there are repeatable problems, but I've heard no
>coherent explanation of what might be occurring.

The NYT article's symptomology bears out across many reports from a
variety of sources.

>The thing that seems to be consistent is that left handed users have
>more reported problems than right handed users.

That would be apocryphal, at best.

The short answer is that fashion trumps technology. The rising trend of using the iPhone as an eReader flies in the face of what was formerly a nebbish activity. Fashion forced the turnaround, not the technology (I've been reading books on my Palm Pilot for 6 years - I have not suddenly become an ï¿½ber-hip literary savant overnight by virtue of that trend as anyone here will quickly testify.)

The only thing that remains a mystery, for me if for no one else here, is the literal specification of the antenna. Google (gasp) fails me.

And that does seem to be the crux of the matter. What is the antenna?
And what does it interact with that's not, be it part of the phone or
part of the user?

Can anyone make a recommendation, based on actual training and experience, as to what width and thickness of copper strap would be needed as the down conductor from the antenna mounts at the peak of my house roof, some twenty five feet above local terrain. I have a a mount for an antenna at one gable end and a mount for a weather station sensor array at the other. What thickness and width should I use in the earth between the two Grounding Electrode Systems. I will drive five eighths inch copper rods, each eight feet long as far out from the foundation as I can get them or eight feet were possible. On one end that will be only six feet due to the proximity of the property line. At all of the other rod locations I will be able to keep them at least eight feet from any underground obstructions. To compensate for the proximity to the foundation wall to the first rod I will use rod couplers and drive it to hard rock or sixteen feet whichever comes first. I'm guessing that in keeping the remaining rods at least eight feet out from the foundation and sixteen feet apart that I will only have four rods total in a ring around the back side of the house. What is the best way to attach the copper strap to the support masts and eve brackets themselves? Do you know of anything that will make a good connection to the one inch galvanized iron pipes that I'm using for support masts?

Can you recommend a technique for bonding the interior grounding buss at the operating position to the exterior vertical copper strap. I have no idea how that is usually done.

Hi Tom,

The antenna is reported as being the metal trim that surrounds the perimeter of the phone. As that is much too large for the frequencies involved to be taken literally, there is more to the story that remains clouded. Maybe I'm wrong....

If the loop (or dipole) is suitably matched, it doesn't give much polarization diversity. Perhaps no phone does anyway.

Insofar as being "part of the user," we well know the EM of HTs and the hand/body contribution. If such were the case, then this would be an agnostic problem that users of all mobile phones would complain of (which mildly refutes what the gadget blogs dismissed). On the other hand, the ï¿½ber-hip, whose complaints are more vocal for their "pain," would be outraged at the notion of their simply enjoying the identical experience of techno-trash. Amazing what a 10 fold cost differential brings to your perception of quality of service.

Hi Tom,

Consult the NEC code for your area. I have never seen them specify
strap in any situation, and don't try your own interpretations of what
"continuous"or "direct" means.

In this part of the world, we have an Australian / New Zealand Standard (our version if you like of ANSI, BS etc) which explains the rationale behind lightning protection, a method of estimating the downcurrent for protection design purposes and a process for designing down conductors.

Broadly, the scheme is that downconductors are designed to withstand a few donwstrokes in quick succession without melting the down conductor. If you work from a peak current of 20kA, it would lead to a down conductor in copper of at least 25mm^2 which is about #2 to you folk.

I regularly see hams recommend much thinner down conductors, and can only assume that there is not regulatory guidance or requirement, and I wonder at the effectiveness of using #6 as often recommended, especially aluminium as is often the case. Note that reducing conductor size is a double whammy, you increase the resistance (so the power), and decrease the mass that has to be heated to melting point, and so the energy required.

But, firstly, you should determine if there are regulatory requirements, such as NEC etc.

The question of equipotential bonding conductors ought be dealt with in the same way, though that is not to imply that they will be the same size.

Owen

I don't remember the sources but I have concluded that the Grounding
wire should be no smaller than #6.

More than 8 feet of ground rod is of little consequence.

All ground rods should be tied together. Don't put your house between
two electrodes!

The ground rods are better directly under the structure that they are
protecting.

The system does not absorb massive high energy strikes. It starts
bleeding off the energy before the strike builds and thus minmiizes
the effect.

Home improvement stores sell #6 wire, ground rods and connectors.

If you are going to get crazy with a grounding system, ground rods
should be spaced their length. 3 rods can be placed to form an
equilateral triangle. Other geometric arrangements that build on the
triangle pattern are good. An example would be a hexagon representing
6 triangles with a rod at each node. Cant think of the name of the
company right now but they make a lot of lightning suppression and
grounding equipment and have free downloadable info. Im sure googling
lightning arrestor will get it for you.

Exactly! May often see during an electrical disturbance little spikes
off the top point of a lightning rod doing its job.

I've been through many 'lightning events' in my day with the closest
direct strike to a neighbor's tree. Also a former wife in my old house
that was hit after she and new husband had cut all the leads to my
ground rods from high TV antennas.

A drawing of the iPhone 4 I saw recently (I think it was in a recent
SJ Mercury News) indicates that there is a deliberate gap in the metal
rim of the iPhone 4 - the rim that serves as the antenna. This gap is
located near the lower left corner of the phone.

If I understand correctly, the iPhone 4 has a tendency to drop calls
if it's held in a way which allows the user's hand to bridge across
this gap... presumably "short-circuiting" the antenna in some way.
A left-handed grip on the phone would put the user's palm right across
the gap - this may be the worst-case situation.

Applying an insulation of some sort to the area of this gap (an iPhone
case, or duct tape), or holding it in a way which doesn't cause the
hand to bridge the gap, reduces or eliminates the problem.

It sounds as if this iPhone has some sort of dipole or loop antenna
design, which requires that a high RF impedance be maintained at this
point. The low RF impedance of human skin is apparently enough to
de-tune or load the antenna in some way which disrupts its function.

Has anyone run across a web site showing a "tear-down" of the iPhone
4, which might clarify its antenna design?

There are a number of issues here, that are Mutually Exclusive, but added together cause the iPhone4 to seem to have some problems.

Issue One. Apple has already admitted that the Signal Level algorithm, used in the IPhone4 was seriously flawed in how it displayed Signal Level. (Bars) When the Phone displayed 4 or 5 Bars, it may actually only be receiving at a 1-2 Bar Level. This they have corrected with a Software Patch.

Issue Two. The Multi-Band Antenna design in the iPhone4 is a Kludge Compromise at best, and burying it in the Metal Frame where Left Hand users put the flesh against it, seriously detunes it. Apple is in the process of hiring a small group of Engineers, with expertise in this area.

The combination of these two issues seems to cause, what appears to be a High Signal Level, to drop to "No Bars" when some users grasp the iPhone4 in a particular way. The "Simple Fix" is don't hold it that way. The more complex "Fix" is to redesign the Cellular Antenna, and move it to the Top of the iPhone4. This would require that the BlueTooth/Wifi antenna be redesigned as well. Apple is looking to do that in the 2nd Generation iPhone4.

Just remember that Apple isn't particularly adept in the RF Arena, and the iPhone/iTouch/iPad are their only small products that have RF Antennas, this small. Also remember that some of their Laptops, of past years, had some serious Wifi Antenna placement problems, and remember that Wifi at that time was only a Single Band, not a Three Band System,

like the iPhone4.

Just saying.

If it is applicable, it seems that for a Class 1 structure (less than 75'
in height???), the requirement for the main down conductor is 57,400
circular mils CSA if copper, that is about 29mm^2 or #2 conductor.

By contrast, #6 is 26,000 circular mils, has approximately twice the
resistance per unit length, half the mass per unit length, and somewhere
just less than 25% of the stroke current withstand of #2.

You seem to be confusing Lightning Ground, Electrical Ground, and RF
Ground, here, and they are basically three different things. If you
build a Lightning Ground, it may, or may not, be an effective Electrical
Ground. Neither of these will be of any use as an RF Ground, unless you
happen to live in a Salt Marsh. You see Copper Strap Grounds, mostly on
Wood, or Plastic Boats, (ships) used to extend the RF Ground, from the
SeaWater, to the Radio, or Antenna Tuner. Here the Strap becomes part of
the Antenna System, and they need to be engineered, so as to provide as
low of impedance connection, between the two as possible, over the
widest Frequency Range. Some work better than others. Some don't work at
all, and the only way the radio functions at all, is because of Good
Band Conditions.

3079. PL-259 on satellite TV coax?

Newsgroup: rec.radio.amateur.antenna
Date: 2010-07-13 19:59:08 UTC
From: spamhog <n1jpr@hotmail.com>
Message-ID: <2c5579a9-50ee-4bf2-93da-14c08c629c8b@t10g2000yqg.googlegroups.com>
Source record: 8429

I must replace the 100+ ft. coax run in a receive-only antenna system that includes a Transi-Tap transient discharger and a Magnetic Longwire Balun impedance transformer, and both have SO-239's.

It used to be RG-58, but foam-dielectric 75-ohm sat-TV coax is everywhere, low-loss, well shielded, cheap etc.and I am sure I can live with the extra mismatch.

However, its shield is aluminum foil. It can't be soldered, so the plug has to be twist-on or maybe crimp-on type. The center conductor is copper or copperclad and therefore can be soldered.

Years ago I did use things that looked like screw-on PL-259's on the 300+ ft. sat-TV coax run that feeds my homemade T2FD. They work perfectly, but I'd be darned if I can find some anymore around here. So I have to buy online unseen, if I can find any. I located exactly one expensive supplier, in the UK, that lists "twist-on PL-259's for RG-58" and they don't look like mine.

QUESTIONS:

- Do twist-on / crimp-on PL259's for RG-58 still exist?
- Do they go by any special name I can't guess?
- Whatever they're actually called, do they fit sat-TV coax?
- Suggestions for suppliers? Or should they be available everywhere?

I hope I hadn't chanced on a nonstandard type!

Thank you in advance!

Aren't cell stations vertically polarised. The one near me is, and one
of the IF's is smack on 144.005 Mhz.

From a casual look at the phone the metal band seems to be a continuous loop. Its unlikely that there is a physical coupling between it and the RX/TX, so any tuner or coupling is going to be affected by the hand grasping it. Since suggestions have been made to hold the phone in a different place, I would guess that the coupling method is suseptible to adsorbtion effects and that the hot parts are near the base of the phone.

FWIW Every mobile phone I've played with has the antenna and coupling circuitry near the top behind the display.

Not any more.. recent phones (last several years) put the antenna at the
bottom to reduce the SAR number, since the top of the phone is next to
your head, and the bottom isn't. There's a really good explanation from
a guy who does, oddly, wireless device antenna design consulting..

We had a long discussion about this about a month ago.

The short of it is to buy the appropriate COMPRESSION connectors (not
crimp on or screw on) ones and use adaptors.

You have to make sure you get the right ones, the ones for RG-59, RG-6 and
RG-6QS are different. F connectors are easy to find and cheap, BNC ones are
harder to find and more expensive.

Geoff.

Hi Bruce,

Jim's second link (which I quoted in my response to him) gives very
specific signal levels. Aside from that, and as is obvious by the
numbers, the "bars" are merely window (with apologies to M$) dressing
in any phone (except as a RF exposure risk indicator).

A bumper would seem to mitigate the risk. Conformal coating would to
some lesser extent. All-in-all, the amount of metal seems to be
consistent with best engineering practices (but, perhaps, not best
consumer packaging practices).

If the phone is disturbed by touching with dry skin, a thin insulating layer won't help. At cell phone frequencies, the capacitive coupling will have less impedance than skin.

My new antenna can easily handle this job.
You make it for the lowest frequency and it will handle all the
frequencies above at a constant impedance..... and with more gain and
the radiater smaller in size!

No!
Total resistance = R1+ R2 The trick is to reduce
R2 in value so more current is being applied to radiation. Very simple
my dear Watson.

And he tells you nothing. And he provides no proof.

The master of vaportennas.

The rumor I heard was that they tried to put in a "better" antenna to
cure problems with dropouts. While it does have more gain it is
sensitive to the way it's held. Basically they traded one problem for
another.
Any confirmation or rebutal would be appreciated

My new antenna can easily handle this job.
You make it for the lowest frequency and it will handle all the
frequencies above at a constant impedance..... and with more gain and
the radiater smaller in size!
****
-
Sounds great. Where can we see the construction details?

Waiting on patent issueance. I have put details out before but in
general hams believe every thing is known and then fire insults.
Frankly, history shows a lot of fraud in antenna new design such that
hams have given up on improvement so I am not to quick on providing
details up front any more.

There's a whole raft of issues..

One is that cellphones aren't analog FM anymore, so they suffer from the "digital cliff" problem.. If the Eb/No is good enough that the FEC works, then it works great, but a dB or so worse, and it doesn't work at all.

This is so different from most people's practical experience with communications that it is disconcerting. E.g. if you walk away from me while talking, your voice gets fainter and the SNR gradually drops, but it's not like you've walked out of the "cone of silence" where it goes from fully intelligible to not at all intelligible in milliseconds.

And, the fact that this happens on a packet by packet basis means that at the threshold, it "stutters", which is also non-intuitive and non-physical.

And then, the cellphone companies have managed to convince us that really crummy sound is ok, even at the full bit rate of <8kpbs. The voice codecs are impressive, but face it, it still doesn't sound like 56kbps u-law or 25 kHz NBFM, what used to be called "toll-quality"

Jim. Thanks for the above links. The Youtube vid was most interesting.
I certainly wasn't aware of the gaps in the metal banding nor of the SAR
requirements.

Yep ! Totally drowns out any signals. A waste of time complaining.
Leakage signals are within spec, according to them.
Anyway I've now given up trying and taken the antenna array down.
To be honest its been some time since I was last active.

i hope this is more interesting than your pick-up-sticks patent, i
still get a good laugh at that one when i read it... amazing what bull
the patent off will pass through.

And then there's the PSTN ala 2010. We have been discovering a lot of new things about that that we suspect even the carriers haven't noticed, or at least appreciated. And it's all started showing up in the last year. Like average LD call completion failure has been 4% for 10 years. Yup it's actually that high. Except this year it's 6%. And possibly still climbing. Can't tell you the test conditions (NDA needed), but it's millions of calls per year.

One of the first odd things we noticed was the occasional location code 3 from the supposed destination. That one is now obvious, but the first time you see it it's very perplexing.

And more things are showing up, mostly disturbing if you expect the PSTN to remain the relatively predictable thing that it's been during the SS7/TDM/ISDN era. So much is changing we are making a new training program for our analysts on how to recognize what's now going on versus what used to go on.

Here's my wild guess as to what's happening, borrowed from my posting
in ba.internet and alt.cellular.attws. Apple announced that there's
going to be a press conference on Friday, where they'll announce
something. Note that I goofed on the location of the wi-fi/BT
antenna, but I'll leave the mistake here for now.

On Wed, 14 Jul 2010 13:05:27 -0700, AES <siegman@stanford.edu> wrote:

>active circuitry still works OK?

Nope. My wild guess(tm), based upon what little I can extract from
the FCC ID page and from the iFixit autopsy, is that something drastic
is happening in receive. The -30dB (that's 1000 times drop) in signal
appears in receive, when you're NOT making a call and the xmitter is
inactive. Well, the xmitter is sending keep alive bursts every few
minutes, but nothing more. Methinks it's a receive problem, not xmit.

I'll go out on a limb and suggest that the receiver front end
(probably a GASFET or HEMT) might be a bit regenerative (border line
oscillatory). This gives it lots of gain, but only if nothing else
changes. In effect, the antenna becomes part of an oscillator
circuit, where the oscillatory conditions are partly provided by the
antenna Q (i.e. antenna efficiency).
<http://en.wikipedia.org/wiki/Regenerative_circuit>

Touch the antenna, and you reduce the antenna Q. The front end stops acting regenerative (barely oscillating), and the sensitivity drops like a rock. It's the only explanation I can conjure the will cause a -30dB drop in received signal. It's been demonstrated (by me and others) that strangling the antenna of other cell phones drops the rx signal up to -10dBm (10 times drop). That's what I would normally expect to see from touching a cell phone antenna. However, the -30dB drop of the iPhone 4 requires some extra circuit design screwups. Unfortunately, detecting the regeneration is going to require internal probes, test fixturing, and plenty of expensive test equipment.

There's another related possibility. Most of the finger tests have been with the finger bridging the gap. That means they're touching BOTH the cellular and wi-fi/BT antennas. It's obviously the hot end of the cellular antenna, but I can't tell if it's the hot end or ground end of the wi-fi/BT antenna. If the hot end, another possibility it that coupling to the 2nd antenna causes this antenna to radiate into the case, thus causing the cellular front end to oscillate. If the oscillations are bad enough, the signal level will be high enough to induce blocking (overload) in the cellular front end. This can be easily detected with a spectrum analyzer probe in the vicinity. If touching/bridging the antennas causes a new signal to appear on the SA, that's the problem.

It would be very interesting to know if touching ONLY the cellular part of the antenna (the part that goes up the side of the phone), and not the wi-fi/BT antenna (bottom of phone), causes the same drop in signal. It would also be interesting to test the wi-fi signal strength to see if it's effected by touching its antenna.

I have a few other guesses, but these are the best I can currently conjure at this time.

>[I'm an EE, but with no RF circuitry experience, much less any cellphone
>experience. So, I can understand this happening with an active
>transmitting circuit -- though I have somewhat more trouble seeing how
>it would interfere in such a sensitive way with a passive receiving
>antenna.]

Think regeneration and borderline oscillation.

The bad news is that if Apple stabilizes the rx front end, and eliminates the oscillation or regeneration, my guess(tm) is that the resultant phone is going to have a serious rx sensitivity problem. If you look at the cellular antenna in the iPhone 3G and other internal antenna cell phones, they're not very simple looking devices. Lots of strange lumps, traces, pads, and oddities, all designed to optimize performance in the 800/900 and 1800/1900 MHz bands. Getting them to look like 50 ohms for minimum VSWR is also important. Lots of articles in the IEEE Antenna and Prop proceedings on the topic of cramming a dual band antenna in the smallest possible package.

On the other foot, the iPhone 4 antenna is crude. As far as I can tell from here, it's a crude monopole (single wire) antenna. There's no matching circuit for VSWR reduction, and no attempt to optimize performance in the desired bands. I might have missed something in the dissection, but all I can see is an end fed monopole, without a counterpoise or underlying ground. Such an antenna is going to have resonances at odd frequencies, and miserable antenna efficiency.

Disclaimer: I haven't found anyone willing to let me tear into their iPhone 4 yet, so all the above is guesswork.

On mine the top is against your ear and the bottom against your cheek
or upper jaw bone and I'm keeping it until it dies, but those kind of
gadgets have a rather limited life around me. I just want a phone with
voice mail. I have a camera thank you, and it doesn't have a tiny
crappy lens that makes anything much over 1 megapixel nothing more
than bragging rights. I don't want texting, The only thing I need is
the ability to call and be called. I don't need a PDA either.

Even in the old days when we had to use the day planners and even go
to school on them, after the class I dumped everything out of it
including the calendar and picked up a new interior from the stock
room. Threw out every thing I didn't need and used it for a note book
at meetings. To me a day planner would be about as useless and my
profession was a computer systems project manager up until I retired.
It's also my degreed field.

Hi Jeff,

Regenerative designs inhabit the naked edge of
amplification/oscillation. You've already said as much. It has to
be, thus, a design feature and not a hack. Otherwise every third one
is going to break into oscillation and the FCC (or test lab) would
have certainly picked up on that. Further, if it is designed in, you
can observe that in the design. Special testing methods are too
elaborate to explain this. Regen is not a design feature left to the
vagaries of production variation in parasitic coupling.

If I'm wrong and Apple does use parasitics to encourage regenerative
feedback, then they may introduce a lanyard for hanging the phone
around the neck and call it the lavaliere option. No doubt they will
sell plenty of mirrors to see it, and someone will come out with an
image reversal app. Can a stylus be far behind? Whoops! It will
have to be chopstick for squeezing and expanding images.

3106. The meaning of 'Radiation Resistance'

Newsgroup: rec.radio.amateur.antenna
Date: 2010-07-15 08:14:36 UTC
From: Owen Duffy <none@no.where>
Message-ID: <Xns9DB6B98B269BEnonenowhere@61.9.134.55>
Source record: 8356

I note some variation in the use of the term 'Radiation Resistance' (Rr) that suggests that it has different meanings to different folk.

One suggestion is that it is the resistance seen by a transmission line connected to an antenna that expresses its coupling to distant regions of space.

If that is the case, Rr would not capture energy that is lost in reflection from real ground. So, Rr would be the sum of power in the far field divided by RMS current squared.

If indeed it is the "resistance seen by a transmission line", then the current above would be the current at the end of the transmission line.

Does the term have an accepted single clear meaning? Is the above correct?

Some implications of the above are that:
- Rr of a horizontal half wave dipole with zero conductor loss, above real ground, would have Rr less than R at the feedpoint by virtue of some loss in waves reflected from real ground;
- Rr of a half wave folded dipole of equal conductor diameters would be around 300 ohms.

Thanks
Owen

3107. Slim Jim v J Pole

Source record: 8357

Hi all

I have just modelled both the Slim Jim antenna and J Pole antenna using MMANA-GAL at the same frequency (145MHz) all other parameter equal and was some what surprised that they appear exhibit the same gain and radiation pattern. Based on an article I read in a English magazine many years ago I have always believed the Slim Jim had a slight edge over the J Pole. Wonder if others had a similar view and if my modelling is correct are there any advantages with the Slim Jim design?

<snip>
Hello, and I don't find any ambiguities in any of my various EM and antenna theory textbooks. FWIW, from the IEEE Standard Dictionary of Electrical and Electronics Terms:

"Radiation resistance (antenna). The radio of the power radiated by an antenna to the square of the rms antenna current referred to a specified point. Note: This term is of limited utility in lossy media."

So if we're looking at free (in vacuo) space the radiation resistance is simply a "load" resistance component that accounts for where the radiated power goes. The radiation resistance doesn't include any other resistive losses in the antenna structure/proximity operating environment that may also be dissipating source power introduced at the feedpoint of the antenna. An aerodynamic analogy would be the distinction between "induced" drag (the price paid for "lift") and "parasite" drag, which are both components of the total drag.
Sincerely, and 73s from N4GGO,

Some websites indicate that the only significant difference is that the
Slim Jim has a somewhat wider bandwidth. Unfortunately, I can't
instantly find a good reference. Here's one, but not too good.

Owen,

I like the IRE definition, which according to W8JI is: "The total power radiated in all directions divided by the square of the net current causing the radiation".

That definition draws a distinction between Rrad and the resistive component of the feedpoint impedance; it makes the Rrad of a folded dipole 75 ohms, not 300 ohms; and it avoids some of the errors folk make in assuming that "folding" a vertical can reduce ground losses.

73,
Steve G3TXQ

Owen
Can I suggest that you look at things differently?
Radiation is created by the acceleration of charge
which effectively that which creates an acceleration of a particle
such as a bullet from a rifle. The reaction to the firing of the
bullet is the recoil
which is considered as the resistance to radiation.
If you expend energy in other places to get to the point of firing
they can only be referred to as losses.
Thus radiation is a point vector and should not be confused by
multiple vectors that create a plasma.
All radiation equations are formed by the use of boundary equations
which requires recognition
of vectors or point charge and NOT by acceptance of the term "waves."
As an illustration, a superconductive material has the minimum
resistance possible to ensure the credibility of Ohms law. This

resistance has nothing to do with "dc resistance" because current flow is at or near the surface because of the destruction of skin depth resistance phenomina, which also means the cancellation of magnetic fields.(Not destruction as the magnetic field is transformed into a energy bank)
Thus ejection of particles can be considered as purely that of the displacement current formed.
Expansion of static laws to those of dynamic form
establishes the use of particles with the use of boundary laws (vectors) together with conformety with Classical laws.

I doubt they're using regeneration or some such similar scheme (too hard
to control for manufacturing variability)..

However,
the idea of self interference is interesting... (e.g. your finger
couples the WiFi to the cellular front end, which blocks)

It could even be as dumb as a dc bias shift thing (save a penny by
leaving out the capacitor, oops, that removed the DC block)

As far as match goes, in very compact systems, the idea of matching 50
ohms goes out the door unless one of your components happens to be 50
ohm impedance.. It's not like they're stringing together building blocks
with SMA connectors inside there. Lots of these RF circuits are
implemented with differential in and out these days, and the Z is
whatever it happens to be.

I goofed slightly. The Anandtech article shows -24dB maximum signal
loss.

>Regenerative designs inhabit the naked edge of
>amplification/oscillation.

Not designs. I don't think it was intentional. Someone else
mentioned that Apple was so much into security on the iPhone 4, that
prototypes were tested in a similar case made to look like an iPhone
3G. That implies that there was little field testing in the new case.

>You've already said as much. It has to
>be, thus, a design feature and not a hack.

I beg to differ. Nobody wants oscillatory effects in the front end of
their receiver. They're unstable, vary with temperature, are
difficult to control in manufacturing, and will probably make the
device fail Part 15 incidental radiation test. Designing a front end
that's unconditionally stable with any antenna load does not yield the
optimum sensitivity. If you want the best performance, amps that are
unstable at specific loads will give better NF and gain.

>Otherwise every third one
>is going to break into oscillation and the FCC (or test lab) would
>have certainly picked up on that.

Maybe. However, one would think that someone would have done a field
test with the final iPhone 4 and noticed that touching the antenna gap
produced a major signal drop. Also, FCC test are not preformed with
human hands wrapped around the phone due to the limited supply of
dismembered hands suitable for testing.

>Further, if it is designed in, you
>can observe that in the design. Special testing methods are too
>elaborate to explain this. Regen is not a design feature left to the
>vagaries of production variation in parasitic coupling.

That might partly explain why some users claim that there's no call drop effect when they touch the antenna gap. Of course, users in strong signal areas are not going to see a dropout, while weak signal areas are going to be much worse.

Incidentally, when Consumer Reports ran a test with the rubber ring thing, they slipped and didn't have the technician stand in front of the test equipment this time.
<http://blogs.consumerreports.org/electronics/2010/07/apple-iphone4-iphone-4-bumper-case-fixes-antenna-issue-problem-signal-loss-tested-verified-consumer-reports-labs-quick-fix.html>
<http://802.11junk.com/jeffl/crud/iPhone4-cmu200.jpg> (normal)
<http://802.11junk.com/jeffl/crud/iPhone4-cmu200-hand.jpg> (with hand)
It's a Rhodes and Schwarz CMU200.
<http://www2.rohde-schwarz.com/product/CMU200.html>
I'm not familiar with the operation. The "Reported Power" appears to be the signal generator output power (because it doesn't change when the antenna is touched). However, I can't devine what the "Avg" or "Peak Burst Power" means.

Also, note that the difference in (something) between the first photo (+16.4dBm) and the hand on antenna measurement (-11.7dB) indicates a -28dB drop in signal level. Ouch.

>If I'm wrong and Apple does use parasitics to encourage regenerative
>feedback, then they may introduce a lanyard for hanging the phone

>have to be chopstick for squeezing and expanding images.

We'll find out after the press conference on Friday. My suggestion was to ship a rubber glove with the phone. I also suggested gluing a plastic thumb tack to warn against holding it improperly. Also, a low signal warning tone. Others have suggested tape, rubber prophylactic bump guards, duct tape, warning labels, rebates, bribes, and external antennas:
<http://gizmodo.com/5581253/there-fixed>
Unfortunately, that will require running the FCC type certification tests again.

I'm not suggesting they did it intentionally. I'm suggesting that the
front end is unstable and that nobody noticed.

>However,
>the idea of self interference is interesting... (e.g. your finger
>couples the WiFi to the cellular front end, which blocks)

I was looking at the FCC ID web site photos again. I can't even tell
which end of the antenna is hot or ground, much less where it's fed.
If the hot end of both antennas are facing each other, it's certainly
possible. However, if Apple did that, they wouldn't need two separate
pieces of metal for the two antennas. They could simply declare some
point along the frame as being the official ground point, and have the
cellular antenna go one direction, and the wi-fi/BT antenna go the
other. Because they didn't do that, my guess is that the hot end of
the cellular antenna is next to the ground end of the wi-fi/BT
antenna.

>It could even be as dumb as a dc bias shift thing (save a penny by
>leaving out the capacitor, oops, that removed the DC block)

Methinks not. The duct tape solution just reduces the effect, not
eliminates it. Assuming duct tape to be a good insulator, that would
also suggest that it's not a DC effect.

>As far as match goes, in very compact systems, the idea of matching 50
>ohms goes out the door unless one of your components happens to be 50

>implemented with differential in and out these days, and the Z is
>whatever it happens to be.

If you look at the inside photos of the BCG-E2380A on the FCC ID web
pile,
<http://www.fcc.gov/oet/ea/fccid/>
(don't forget to include the "-" as part of the product code), there's
a module labeled "Acoustic and Cellular Antenna Feed" on Pg 9 and 10.
<https://fjallfoss.fcc.gov/eas/GetApplicationAttachment.html?id=1300576>
There's a coax cable going across the module, which I assume is 50
ohms.
<http://802.11junk.com/jeffl/iPhone4/iPhone4-accoustic-and-cellular-ant-feed.jpg>

It doesn't appear to do any more than connect a tiny coax connector to the RF module on one end, and a gold screw lug to the frame antenna on the other. No matching in between. Due to the coax, someone must think the antenna is 50 ohms at 800/900 and 1800/1900.

I've never seen a differential RF amp in a cell phone. If so, I would expect either a balanced antenna feed, or possibly two antenna connectors.

Disclaimer: I'm doing quite a bit more guessing than usual. Please do not treat the above as authoritive.

I recall reading though Cebik's excellent web pages on J-poles and
variants thereof, a few years ago, and his modeling results pretty
much corresponded to yours.

Compared to a simple J-pole with the radiating element consisting of a
single wire, the "Slim Jim" variant has two parallel radiators (e.g.
the two conductors in a twinlead or window-line). The two radiators
may or may not be shorted together at the top.

As far as I can tell, electrically, the addition of the second
radiator doesn't make much difference in how the antenna behaves. It
doesn't change the overall shape of the current distribution curve on
the radiator... just divides the current flow between the two wires.
Since the current curve shape is the same, and the vertical span of
the radiator doesn't change, the gain pattern will be the same.

It does seem to have the effect of making the radiator "fatter", which
can both lower its resonant frequency a bit, and make it a bit more
broad-banded.

I believe that for most purposes, the two antennas can be considered
equivalent - they're both end-fed half-wave radiators, and will have
the gain pattern you'd expect from a half-wave dipole. Both are
equally vulnerable to having their patterns disturbed by current flow
on the feedline or the mast, if you don't take some precautions to
isolate these (e.g. via chokes, a half-wave coax balun, etc.).

Consumer Reports to Apple: "You've been served!"

The long and short of it is that Apple treats its product design like
bulimic runway models. It's up to you to see they get as fat as
necessary to live a productive life.

In other words, there's no room left inside the iPhone for an antenna
and it ruins the esthetics for it too bulge. So, if you don't want to
be viewed as part of the pocket-protector crowd, suck up and hold your
phone like Lady Gaga.

The difference is negligible. They both suffer from unbalanced feed
currents and thus feeder radiation. There is or was a commercial
design that attempted to reduce that.

Hmmm. The last statement suggests that, as defined, it is not clear and
unambiguous in the real world because the real world involves "lossy
media".

The "reference to a specified point" suggests that if one gives a value for
Rr, it is necessary to also state the reference point. Is that what it
means?

This is exactly the lack of clarity that is troubling me.

This does not address the issue of ground reflection that I mentioned.

I am not an aerodynamics type, so drawing that analolgy only helps to
confuse. You might as well use optics!

I know you are trying to be helpful John, but the IREE definition doesn't
seem to clarify the issue.

To put some numbers on my first example, if I have an NEC model of a centre fed half wave dipole with zero conductor losses, mounted over real (ie lossy) ground, and feedpoint R at resonance is say, 60 ohms, and total power in the *far field* divided by I^2 is say, 50 ohms, is Rr 50 ohms? Is the power "radiated" from such a dipole ONLY the power that makes it to 'distant space', or is radiated power input power less dipole conductor losses?

The IREE definition suggests that I need also to state that Rr is 50 ohms at the centre, and the term is is of "limited utility" (not unambiguously clear?) because of the lossy ground reflections.

If indeed the term Radiation Resistance is only applicable in lossless scenarios as suggested by the IREE dictionary, what it a clear and unambiguous language for the real world?

Cheers
Owen

Modeling of J-poles and ground plane verticals shows considerable mutual coupling to the feedline, and the Slim Jim almost certainly behaves the same in this regard. The amount of common mode current this induces and consequently the amount of pattern distortion it causes depends on the feedline length and its path to ground. When the current is significant, you'll probably need two current baluns (common mode chokes), one at the feed point and the other about a quarter wavelength down, to reduce it to a low value.

I theorize that the dependence of common mode current on feed line length is a possible cause for the widely varying reports on how well a J-pole radiates -- some people get lucky, some don't.

Hi Owen,

All of this neatly fits into Broadcast Band transmission where the
current pulse (we are now into the shadow zone of SWR) occurs at the
feedpoint of an antenna that is conventionally a quarter wave tall,
the current can be measured, and the far field power is known. The
matter of "lossy media" has been studied (BL&E) and that variable
reduced by good engineering practices (which brings us back to the
known far field power).

>The "reference to a specified point" suggests that if one gives a value for
>Rr, it is necessary to also state the reference point. Is that what it
>means?

The "reference" is typically the current node. It gets messier with
more complex antenna design.

>This is exactly the lack of clarity that is troubling me.

This implies the more complex designs following (or not following)
what you reject as "rules of thumb." Or at least their appearance.
I'm sure there are long and elaborate academic treatises that explain
the current node current measurement in relation to the known radiated
power. I haven't read any of them that I can glibly quote here.

>This does not address the issue of ground reflection that I mentioned.

I will return to your original and comment to that:
>>Some implications of the above are that:
>>- Rr of a horizontal half wave dipole with zero conductor loss, above
>>real ground, would have Rr less than R at the feedpoint by virtue of some
>>loss in waves reflected from real ground;

There are two mechanisms hiding in one description. The ground is
lossy - period. The ground is reflective - period. These are two
different issues in regard to radiation resistance. The Rr is not

ground loss although the measure of Rr may be corrupted by Rground. That is a problem of separating out the variables. Others have described that. The reflection from ground may upset the measure of Rr as well, but if that does not upset the total power, and the current node can be measured, then you still have a way to quantify Rr.

>>- Rr of a half wave folded dipole of equal conductor diameters would be
>>around 300 ohms.

I thought someone else preceded this discussion with Tom's explanation. Maybe it went unread, or unrealized. So, in other words: A folded dipole/monopole is a current transformer. That transformation ratio is driven, in large part, by the ratio of the diamters of the conductors. You have acknowledged as much in your own specification of equal sized conductors. Having said that, the transformer is also transforming the Z of the load (Rr + Rground) by a square law. The usual sense of current node has been lost in a more elaborate design, but the transformation of it returns us to the usual Rr.

If I take a half wave folded dipole immersed in some environment where the ambient noise temperature is T, and attach a load directly to the feedpoint, the load power will be maximum when it is about 300 ohms rather than about 75 ohms, and the noise power density due to ambient noise would be K*T*300 W/Hz rather than K*T*75 W/Hz. If Rr is the (virtual) resistance due to coupling of the antenna with distant space, then surely this example suggests that Rr is 300 rather than 75 ohms.

(If I performed the same experiment with a plain half wave dipole, the load power will be maximum when it is about 75 ohms, and the noise power density due to ambient noise would be K*T*75 W/Hz.)

To some extent, my question comes to is Rr at a 'defined' point, and is that point the interface between non-radiating feed line and the radiating structure.

Yes, you could argue as Richard states that a folded dipole includes an integral transformer, but then, the generalised outcome of that argument is that all antennas are impedance transformers, Rr could be some agreed fixed quantity located at a great distance in space, or even more confusing, an non-shared arbitrary value, and that key to it all is some new concept of the antenna impedance transformation ratio.

The notion that Rr is defined at a virtual point that is between any deemed integral impedance transformation and the rest of the radiator, rather than defined at the physical feedline / radiator interface doesn't seem too sensible.

Radiation resistance is pretty much what the writer wants it to be. Consequently, it has to be explicitly each time it's used whenever an ambiguity might arise. It's simply a resistance whose "dissipation" (absorbed power) is the amount radiated. Most writers would probably argue that power lost from the near field to nearby lossy objects such as ground never got radiated, and therefore the corresponding resistance should be considered loss rather than radiation resistance. The presence of nearby ground, however, can also change the value of the remaining resistance due to mutual coupling and alteration of the current distribution, so a particular antenna doesn't have a single inherent value of radiation resistance independent of environment.

As for the location where radiation resistance is defined, I believe it's common in AM broadcasting, for example, to refer the radiation resistance of a monopole to a current loop (maximum). If this is a different location than the feed point, the resistance (neglecting loss) at the base will be different from the loop radiation resistance. The ratio of base radiation resistance to loop radiation resistance will in fact equal the square of the ratio of loop current to base current. So radiation resistance measured at the base can be "referred" to the loop by scaling by this ratio. (The power "dissipated" by radiation resistance referred to a loop or any other point has to equal the "dissipation" of the radiation resistance seen at the base or any other point. So Rr has to differ to keep I^2 * Rr constant as Rr is referred to points having different values of I.) The radiation resistance can be referred to any point on the antenna, so the writer has to specify what point is used. But one point is as acceptable as another. It's vital, though, when using radiation resistance, that the current at the defined point is used for calculations. And loss resistance must also be referred to the same point if efficiency calculations are to be made.

Some authors, for example Kraus, consistently refer the radiation resistance to the feed point. But Kraus doesn't explicitly apply the term "radiation resistance" to a folded dipole. There's nothing at all wrong, however, with declaring the radiation resistance of a folded dipole to be ~300 ohms. The power radiated is the current measured at the feed point, squared, times that resistance. It's equally legitimate to declare the radiation resistance of a folded dipole to be that of an unfolded equivalent, or ~75 ohms. If you do, though, you also have to work with the current of the unfolded dipole to make the power come out correct.

A common mistake when dealing with folded unipoles, made by at least several prominent people who should have known better (and marketing people who probably do know better but find it advantageous to be

incorrect), is to refer the radiation resistance to the feed point but the loss resistance to the unfolded equivalent. This results in an erroneous efficiency calculation that incorrectly attributes an improvement due to folding. As I said, you can refer the radiation resistance to either, but if you want to calculate efficiency, you have to refer the loss resistance to the same point and having undergone the same transformation. And when you do, you find that folding fails to produce the often-claimed efficiency improvement.

Roy Lewallen, W7EL

Thanks Roy.

I note you observe similar variation in usage as I note.

Yes, consistency in an application is more important than a common meaning of the term, but a common meaning of the term assists simpler communication.

Regarding say, a base fed folded monopole and efficiency calculations, if the connection to ground is though of as having some actual value Rg, since the current flowing in Rg is twice the feedpoint current, consistent development of the circuit model will reveal the correct efficiency as:

Rr/(Rr+2Rg)

where Rr is the sum of power in the far field divided by feed point current squared. You don't need to fudge Rr to get the result, proper allowance of the power due to the actual current in Rg provides the correct result.

Kraus (Annennas for All Applications) effectively defines Rr as part of his development of the concept of a pair of conductors transitioning from a non-radiating transmission line to an antenna to free space radiation.

He does say "... the radiation resistance Rr, may be thought of as a "virtual" resistance that does not exist physically but is a quantity coupling the antenna to distant regions of space via a "virtual" transmission line."

It is his use of "distant regions of space" that suggests in the case of ground reflection, it is the remaining total power in distant free space after lossy reflection that is used to calculate Rr. The power lost in reflection would be a component of feed point R, but not Rr.

He also states a little earlier "... the antenna appears to the transmission line as a resistance, Rr, called the *radiation resistance*. It is not related to any in the antenna itself, but a resistance coupled to the from space to the antenna terminals." This seems fairly clear to me that he defines radiation resistance to be at the transmission line / antenna interface.

Both of these statements by Kraus are simple, but would seem to be capable of application to real antenna systems. I can't immediately think of exceptions (game on???).

In Kraus's language, ground reflections might reasonable be considered part of the 'antenna' since they influence its pattern and loss, and loss in the ground reflections is due to resistance "in the 'antenna' itself" and so excluded from Rr.

Is there anything in Kraus's statements that is wrong, or my interpretiohn of them.

Owen

Sorry, that is plainly wrong. Clarity struck whilst having breakfast, the
received power of a matched system should be independent of R.

Noise power density is simply K*T W/Hz. There is no R term.

The text should read...

If I take a half wave folded dipole immersed in some environment where
the ambient noise temperature is T, and attach a load directly to the
feedpoint, the load power (due to ambient noise) will be maximum when it
is about 300 ohms rather than about 75 ohms. If Rr is the (virtual)

In real world terms radiation resistance is measured by the vector
that overcomes radiation resistance or the conveyance of
communication. This compels the measurement of that which is
accelerated as it is an action and reaction type vector. If one
doesn't have a measurement of the mass that is being accelerated then
radiation resistance itself cannot be supplied. What happens
to the accellerated mass has no connection what so ever to the
accelleration vector.To find the accelerating vector one must first
determine the efficiency of the apparatus used and this will vary
dependent on the method used to produce the accelerating vector so
that one can determine the losses. So if we cannot identify that
vector which creates acceleration of charge where the charge is the
measurement of radiation one must first determine what creates
radiation so that the radiation unit can be measured. The bottom line
is
that one must use a superconductor where only the accelerating vector
comprises of the impedance
seen by the time varying current and where the
resistance of the radiating member is divorced from the equation as is
coupling losses in the absence of a magnetic field.

True. But we can't force consistency of a term that's already ubiquitous in the literature with a variety of meanings. Saying it's so doesn't make it so.

Ok, here we go. Remember that efficiency is really a power ratio, not a resistance ratio. It reduces to the familiar resistance formula only when the currents in both radiation and loss resistances are the same.

Let's talk about Rg. An unfolded monopole has a single connection to ground, and we can call this resistance Rg. If Rr is the base radiation resistance, then the same current flows through Rr and Rg, so efficiency = Pr/(Pr + Pg) = Rr/(Rr + Rg) and everything's fine. But when we fold it, there are two connections to ground -- the "cold" side of the feedline and the non-feed monopole conductor. Each has half the original current. The "hot" side of the feedline carries the same current as the "cold" side so its current is half the original value also. You have your choice for Rg -- you can consider it to be the original ground system resistance but with twice the current flowing through it as through the feedpoint resistance; or you can split the original into two equal parallel resistances of twice the value, each with the same current as at the feedpoint. In the first case, you get the equation you posted. In the second, you get Rr/(Rr + Rg). We've basically referred the ground resistance to the transformed feedpoint.

The surest way to stay out of trouble is to always calculate efficiency as a ratio of powers. If you use I^2 * R for radiation power and loss

power, you can't go wrong, regardless of where you choose either R to
be, as long as the I is at the same point.

> Kraus (Annennas for All Applications) effectively defines Rr as part of his

> reflection would be a component of feed point R, but not Rr.

Well, we can get carried away with this, too. Nearby ground sucks power
from the near field and that power is never radiated. The longer
distance ground reflection primarily responsible for elevation pattern
development uses power which has been radiated from the antenna
conductor(s). Is that reflection "distant"? When you calculate an
antenna's efficiency, do you include the power radiated from the
conductor before or after the ground reflection? What about power that's
lost by radiation to space? It's just as surely lost for terrestrial
communication as power warming the ground. Answer: It's entirely up to
you. You could even consider all energy which doesn't strike your
receiving antenna as "loss". All you have to do is clearly state what
you're including and what you're not.

> He also states a little earlier "... the antenna appears to the
> transmission line as a resistance, Rr, called the *radiation resistance*.
> It is not related to any in the antenna itself, but a resistance coupled to
> the from space to the antenna terminals." This seems fairly clear to me
> that he defines radiation resistance to be at the transmission line /
> antenna interface.

Kraus is consistent with this, but other respected authors use the term
radiation resistance differently. The few who use the term radiation
resistance when lossy ground is present, though, seem to regard
near-field coupling loss to ground as loss, and not consider far field
reflection in efficiency calculations at all.

> Both of these statements by Kraus are simple, but would seem to be capable
> of application to real antenna systems. I can't immediately think of
> exceptions (game on???).

As I said above, how distant?

> In Kraus's language, ground reflections might reasonable be considered part

> Is there anything in Kraus's statements that is wrong, or my
> interpretatiohn of them.
>
> Owen

Kraus isn't wrong. Neither are the other respected authors who use the term differently. I'm sorry, but you're looking for something that doesn't exist, and I don't see the point in trying to invent a strict definition just for your own use.

Richard
I will certainly make the installation code compliant. What I was looking for help on was how to make it effective in avoiding damage from lightning. I have read all of the applicable material from the Polyphaser, NIST, and several other sites but what I was hoping to elicit was specific guidance on what size strap to use for the down conductors and what size to use for the ground ring so that they might actually work rather than just comply with the code. I can certainly add any regular wire conductor that would keep the electrical inspectors happy since I already have 2/0 bare copper for the ground ring; were only #2 is required and, the ridiculously undersized, number ten that the code requires for down conductors in hand.

810.58 Grounding Conductors — Amateur Transmitting and Receiving Stations.
Grounding conductors shall comply with 810.58(A) through (C).
(A) Other Sections. All grounding conductors for amateur transmitting and receiving stations shall comply with 810.21(A) through (J).
(B) Size of Protective Grounding Conductor. The protective grounding conductor for transmitting stations shall be as large as the lead-in but not smaller than 10 AWG copper, bronze, or copper-clad steel.
(C) Size of Operating Grounding Conductor. The operating grounding conductor for transmitting stations shall not be less than 14 AWG copper or its equivalent.

810.21 Grounding Conductors — Receiving Stations.
Grounding conductors shall comply with 810.21(A) through (J).

(A) Material. The grounding conductor shall be of copper, aluminum, copper-clad steel, bronze, or similar corrosion-resistant material. Aluminum or copper-clad aluminum grounding conductors shall not be used where in direct contact with masonry or the earth or where subject to corrosive conditions. Where used outside, aluminum or copper-clad aluminum shall not be installed within 450 mm (18 in.) of the earth.
(B) Insulation. Insulation on grounding conductors shall not be required.
(C) Supports. The grounding conductors shall be securely fastened in place and shall be permitted to be directly attached to the surface wired over without the use of insulating supports.
Exception: Where proper support cannot be provided, the size of the grounding conductors shall be increased proportionately.
(D) Mechanical Protection. The grounding conductor shall be protected where exposed to physical damage, or the size of the grounding conductors shall be increased proportionately to compensate for the lack of protection. Where the grounding conductor is run in a metal raceway, both ends of the raceway shall be bonded to the grounding conductor or to the same terminal or electrode to which the grounding conductor is connected.
If metal enclosures such as steel conduit are used to enclose the grounding conductor, bonding must be provided at both ends to ensure an adequate low-impedance current path.
(E) Run in Straight Line. The grounding conductor for an antenna mast or antenna discharge unit shall be run in as straight a line as practicable from the mast or discharge unit to the grounding electrode.
(F) Electrode. The grounding conductor shall be connected as follows:
(1) To the nearest accessible location on the following:
a. The building or structure grounding electrode system as covered in 250.50
b. The grounded interior metal water piping systems, within 1.52 m (5 ft) from its point of entrance to the building, as covered in 250.52
See the commentary following 250.52(A)(1).
c. The power service accessible means external to the building, as covered in 250.94
d. The metallic power service raceway
e. The service equipment enclosure, or
f. The grounding electrode conductor or the grounding electrode conductor metal enclosures; or
(2) If the building or structure served has no grounding means, as described in 810.21(F)(1), to any one of the individual electrodes described in 250.52; or
(3) If the building or structure served has no grounding means, as described in 810.21(F)(1) or (F)(2), to an effectively grounded metal structure or to any of the individual electrodes described in 250.52.
(G) Inside or Outside Building. The grounding conductor shall be permitted to be run either inside or outside the building.

(H) Size. The grounding conductor shall not be smaller than 10 AWG copper, 8 AWG aluminum, or 17 AWG copper-clad steel or bronze.
(I) Common Ground. A single grounding conductor shall be permitted for both protective and operating purposes.
(J) Bonding of Electrodes. A bonding jumper not smaller than 6 AWG copper or equivalent shall be connected between the radio and television equipment grounding electrode and the power grounding electrode system at the building or structure served where separate electrodes are used.

Owen
Believe it or not the NEC only calls for number ten American Wire Gage
(AWG) or 5.261 (mm)2 for protective grounding conductors. Bonding
conductors between electrodes are only required to be number six AWG
or 13.30 (mm)2. So leaving aside the bad joke that is the NEC
requirements I'm trying to get some idea of what best practice might
be.

Would you mind sharing what you base that advise on? Much of it
appears contrary to NIST guidance on protective grounding and current
industry practice.

Bruce
I don't know were your getting the idea that I'm confusing the purpose of the grounding when I specifically asked about lightning protective down conductors. The other places that I have seen copper strap grounds is on the Polyphaser web site. Polyphaser is one of the most respected names in lightning protection for radio installations in the United States. Let me be clear that since I'm using balanced antennas I have no pressing need for an RF ground. Lightning grounding is what I'm interested in and I'm looking for someone with actual field experience of best practice.

Owen
The NEC only requires 5.261 (mm)2 for the protective down conductor
and 13.30 (mm)2 for the bonding conductor between electrodes. Since
those sizes are at best a bad joke I was hoping to elicit best
practice advise on what size the conductors should actually be as well
as advise on how to accomplish the bonding of the interior single
point grounding buss bar to the exterior grounding conductors and
Grounding Electrode System.

Ok, well the question is whether you give it importance, or stay with NEC.
I think it turns out that you have a copy, read it and make you own mind
up.

If it was me, I wouldn't waste the money on an inadequate protection
scheme.

I only did it once but the j-pole design papers often call for the
feedline to be coiled tightly -- a few turns -- just below the feed
point. I have made and used several of these "choke baluns" for HF
because failure to use a balun seems to screw up my VSWR readings.
Does this strictly apply to 2m j-poles, too? I don't know.

I have used 7 turns on 1 inch PVC about an inch below the feedpoint on the Arrow style J Poles I have built. I see no significant change in the SWR when coupling my hand to the feedline over the first 2 meters below the feedpoint on the 2 meter band. Per my version of "significant".

For best results, follow Roy's advice.

This is not a beauty contest for the diversion of inspectors.

Forgive my not continuing to quote you further as I see that it
NOWHERE employs strap in its description of conductors.

Here is a clue. Call up your insurance agent that provides coverage
for your house against lightning strike. Ask him if your policy would
be honored if your home did not conform to code. Ask him how many
claims had been made for lightning damage to homes that did conform to
code.

#6 is a minimum required by code here in the Midland MI area. As it's
a minimum, I would not use anything less than #2 Copper.
>
> More than 8 feet of ground rod is of little consequence.
>
That depends on your soil conditions. Here I'd probably agree as the
soil is usually quite moist and just a couple feet down is just plain
wet.

However a string of ground rods tied together can be quite effective.

>All ground rods should be tied together. Don't put your house between
>two electrodes!

I'd put a circle of them around the house, all tied together every
16', but due to the garage and driveway, that is not possible.
>
>The ground rods are better directly under the structure that they are
>protecting.

I have a 100' 45G 10' from the NW corner of the garage. Tied into it
is a grounding system consisting of 32 or 33 8' ground rods connected
together with over 600 feet of bare #2.

This system consists of a ground rod about a foot outside the concrete
bare in like with each tower leg. The cable is clamped to each tower
leg and comes off in a curve to the ground rod and is extended out in
a straight line at least 80' with additional ground rods every 16'
(give or take a tad) This system also ties into the house electrical
ground. There is an additional run that goes directly from the ground
rod at the base of the 45G to the 25G on the West end of the shop.
From there it goes on around the shop to the mast holding the 144/440
vertical and around the south side to enter the shop to provide
grounding for the station and computers. This also ties the shop
ground (which is on a different electrical feed) to the house ground.

>
>The system does not absorb massive high energy strikes. It starts
>bleeding off the energy before the strike builds and thus minmiizes
>the effect.

Mine has taken at least 17 direct hits that have been visually
verified. All that energy had to go some where.

The bleeding off theory has been pretty well discussed and discarded
on the tower talk reflector. Read up on the Polyphaser site. They have
some good information. Those lightning balls or porcupines have
proven ineffective. The major work for lightning rods and ground
systems is to divert the lightning away from the interior of buildings
and process control systems in Industry.

>
>Home improvement stores sell #6 wire, ground rods and connectors.

Read the new NEC code for tower and antenna grounding. There is a
reason I went with #2.

The Polyphaser site has a tutorial on grounding tower legs and coax
shields. this would be applicable to connecting to the 1" pipe.
Use lots on NoAlox between the strap and pipe.

Lossy media is that which absorbs radiation passing through it. IOW it
heats up. This is different than say the outside air being warmed
through conduction from the earth's surface being in turn heated up by
radiation from the sun.

> The "reference to a specified point" suggests that if one gives a value for
> Rr, it is necessary to also state the reference point. Is that what it
> means?

Hello, and yes, you would have to specify where the quantity applies. Rr
is being calculated as I^2 * Rr = Power radiated. The usual reference
point is the feedpoint of the antenna. Note that the antenna feedpoint
could also be defined to include matching networks and even transmission
line. Of course if these other components also radiate they contribute
to the antenna's radiated power.

>
> This is exactly the lack of clarity that is troubling me.

>
> This does not address the issue of ground reflection that I mentioned.
>

It doesn't matter to the definition of Rr what other agencies may modify
an antenna's characteristics. For example, we measure (at a particular
frequency) the real (resistive) part of its feedpoint impedance. A
portion of that resistance is due to ohmic losses in the earth, antenna
structure, and any other items forward of the feedpoint. The remainder

of the resistance is Rr. In this example the "antenna" consists of the
monopole and its near-field operating environment.

>
Well, I've spent a great deal my professional career as an EE dealing
with USN shipboard antennas and just happen to have ham radio as an
"office" related hobby. As I said in my previous post I don't have a
problem with what Rr means. It seems like a rather straightforward and
simple concept. I think you're trying to read more into it then is there.

> To put some numbers on my first example, if I have an NEC model of a centre
> fed half wave dipole with zero conductor losses, mounted over real (ie
> lossy) ground, and feedpoint R at resonance is say, 60 ohms, and total

> the power "radiated" from such a dipole ONLY the power that makes it to
> 'distant space', or is radiated power input power less dipole conductor
> losses?
>

The radiated (far field) power is what is relevant to Rr. The radiated
power is the power accepted by the antenna designated feedpoint less the
other ohmic (items that are dissipating heat) losses forward of the
antenna feed and in its (near field) vicinity. Also, by "accepted"
power I mean the actual power into the antenna terminals (incident power
less reflected power).

> The IREE definition suggests that I need also to state that Rr is 50 ohms
> at the centre, and the term is is of "limited utility" (not unambiguously

No it doesn't.

> If indeed the term Radiation Resistance is only applicable in lossless
> scenarios as suggested by the IREE dictionary, what it a clear and
> unambiguous language for the real world?
>
> Cheers
> Owen

The definition doesn't say that (cf the word "limited"). Again I think
you're trying to read items, that while possibility contributing to the

measured/calculated Rr value are irrelevant to the basic definition. IOW those other items such as earth grounds if present really ARE part of the antenna. The power radiated by the antenna could propagate as ground wave, sky wave or in combination - it doesn't matter. Sincerely, and 73s from N4GGO,

Parts come from the code books,
some from experience and
some from observation.

The #6 wire is out of the code book. Reason and observation leads to
the conclusion that whatever you use there is the possibility of a
lightning strike that can vaporize it. That also supports the notion
that the charge must be bled off over time (seconds?) rather than
shunted to ground instantaneously. In a moment of lapsed judgment I
installed a ground rod for an invisible dog fence on the opposite side
of the house from the electric service ground. I also allowed the
TV-Internet cable ground a few feet away. Lightning strikes carbonize
cable coax connectors. Dog fence controller factory repair is $40 per
event. After much consideration I ran a #6 wire between the power
service ground and the rods for the dog fence and cable ground rods.
Much thought was given to this because that route involved putting a

conductive path along the floor joists just beneath my bed! I considered the fact that copper plumbing is routinely routed without concern wherever it is needed. No more service calls to the cable company, no more repairs needed for the dog fence controller!

I have concluded that if more than 8 foot ground rods were required for effect or code, the supply houses would be selling them. I cannot argue with redundancy though. THERE IS A POTENTIAL PROBLEM WITH GROUND RODS THAT ARE NOT BONDED WITH AT LEAST #6 WIRE! Common sense dictates that protective system be continuously bled to a common level rather than allowed to build up a differential charge.

My observations have led me to the notion that the frail little #6 wire does not provide the path for a direct strike. It only suggest a route for the strike. A straight direct route is more likely to be followed to ground than a longer twisted route. Lightning is a "boss force". It can and will ionize its own path in a seemingly whimsical manner. A spin-off cable loop has been popular for antenna entry points for many years. This is one of those considerations that may not do anything but it cannot hurt either!

Whatever you do it must:
Meet code, follow the law
Satisfy the Insurance company, don't give them room to wiggle out of a claim!
Enhance safety
Protect your property.

In spite of all the precautions and preparations that you take you can only reduce your exposure to the natural forces in life! My dog Shadow (a black Labrador Retriever) endorses this by retreating to the Master Bathroom during storm conditions. Midnight, (Shadows Cat) concurs by hiding in the basement workshop under those same conditions. I disconnect all ham radio antennas.

At this time I seem to have my problems at bay... but I also have professionally installed lightning rods on the house.

Roger, I like your response better than mine.

It sounds to me like you have the ultimate solution. I arrived at my operating point one step at a time and I quit working on the problem when I quit having problems!

I have a non-Ham friend that lives a couple of miles down the ridge from me that continues to have lightning related problems that may benefit from your advice. I will pass along the Wisdom.

Thank you!

I've seen a couple of postings so far recommending a single balun at the feedpoint. While this takes care of conducted common mode current, it doesn't eliminate current induced on the feedline from mutual coupling. All the single balun does is to insure that the current is near zero at the single point where the balun is inserted. Current is still induced on the feedline, and you end up with a current maximum a quarter wavelength down the line -- the distribution looks just like it does on an antenna (which the feedline has actually become), with the balun location being the end of the "antenna". The balun can even make the induced current worse if the effective common mode open circuit at the balun insertion point results in a more nearly resonant feedline length. The only way to really effectively reduce the induced current to a low level is to break up the resonance of the feedline by inserting a second balun about a quarter wavelength below the feedpoint as I recommended earlier.

Does the velocity factor of the coax come into play when locating the
second
choke or does the outer shield behave like an open wire, VF ~ 1.0?

Perhaps I am slicing the baloney too thin for an average sandwich ;-)

> Perhaps I am slicing the baloney too thin for an average sandwich ;-)

You will often see emphatic advice as to which side of the thing to attach the shield, and which the centre conductor.

In fact, the antenna structure lends itself to an effective integral balun. If you take the feed coax through the bottom wall of the U section, bonding the shield to the tube, and up one side (doesn't matter), exiting at the appropriate point. At this exit, trim the shield and bond it to the tube, and take the inner horizontally across to the other tube and connect it.

If physical symmetry is very good, the balun will be very good.

Nevertheless, as Roy observes, the feedline and supporting structure below the U section is coupled and there is still potential for some level of common mode current.

(To preempt Roy, the velocity factor of the outside surface of the shield clad with a thin layer of vinyl will be close to 1, close enough for the purpose at hand.)

Owen

The news have it:
Apple's new I phone cuts connections frequently due to bad reception.
That happenes when holding the I-phone in a certain way.

http://tinyurl.com/32lp96x

cit:

(01.07.2010)

Antenna engineers, Apple wants you to help with iPhone reception
Are you an unemployed antenna engineer who specializes in wireless
mobile devices?
Are you an unemployed antenna engineer who specializes in wireless
mobile devices? Apple Inc. might have a job for you. The company,
which is under fire for reception problems with its newest iPhone
model and its iPad tablet computer, has posted three openings on its
website for jobs described as "Antenna Engineer-iPad/iPhone." ï¿½ Don't
miss a thing. Get breaking news alerts delivered to your inbox. The
posts are dated June 23, the day before the launch of the iPhone 4,
which customers have been complaining loses signal when held in
certain ways that seem to interfere with the device's antenna. Apple
responded to complaints last week in a statement that said some loss
of reception is common when gripping any wireless device. The
Cupertino, Calif.-based company suggested users avoid gripping the
phone "in the lower left corner in a way that covers both sides of the
black strip in the metal band." Or, the statement suggested, owners of
the phone could purchase one of several cases being marketed for the
device. One iPhone 4 user who e-mailed Apple Chief Executive Steve
Jobs directly about the issue got a response that said, in entirety,
"There are no reception issues. Stay tuned," according to the popular
MacRumors website. Analysts at ISuppli Corp. said similar issues
weren't that common among other smart phones because the antenna is
usually packed inside. The iPhone 4's antenna is a steel frame that
wraps around the device to boost cellular coverage, Jobs said at the
phone's unveiling June 7 in San Francisco. The Apple job description
says candidates "should be able to design antennas suitable for
wireless handheld devices with excellent radiation performance." The
company did not return phone calls or e-mails on Wednesday requesting
comment on the ads. Despite complaints about iPhone 4 reception that
popped up widely on the Internet soon after the phone was released,
Apple sold 1.7 million of them -- a record for the company -- in the
first three days the device was on the market. The iPhone 4 starts at
$199 with a commitment to a two-year AT&T cellphone plan. Apple says
it expects to be selling the phone in 88 countries by September

end cit.

Other sources mention a 100 mio dollar research budget
to fix that Ipod antenna.

Ever heard about diversity antennas, 3dB coupling of
antennas using directional couplers, switchable antenna arrays?

100 mio dollars are out there waiting for you!

It's not that bad a joke.. If the ground connection is good, #10
is plenty thick enough. In fact, it would barely get warm if it
took a strike. Of course, if the connection to ground is bad,
it will be toast. But so would a lot of heavier gauges also..
The connection to ground is the critical factor in such a case.
But I would still follow what the local code says.
The main reason I'm making this post is only to clarify that
under proper conditions, #10 is plenty thick enough to safely
route the strike to ground with no damage to the wire.

... and take *real* care to waterproof the point at which the cable
exits from the tube and the shield is bonded! Buy a tube of
non-acid-containing (metal-safe, "neutral cure") silicone sealant, and
apply it very thoroughly here... squeeze and press plenty of it into
the braid and then form a layer which completely seals the exit point.

If you don't do this, and leave even a small amount of braid exposed
to the air, it will tend to "wick up" moisture into the braid every
time it rains.. The water can even wick its way down to the bottom of
the cable and you can find water dripping out of (or filling up) the
connector at the bottom! Trust me, it really does happen... I found
my lower N connector full of water, and what I swear appeared to be
algae!

I've been watching this unfold over the last week or so and I think Apple has hit the point where you can't have your cake and eat it too. New gadgets are fine, but there is a limit on cell phone reception. It isn't magic but people tend to think it is. I have cell phones all over the place since my wife is a cell phone addict where I could care less. There are dead zones depending on who you have signed up with. I found this painfully true when I was on a bicycle ride in the mountains and two women were talking with a tower in plain sight. My phone would not connect since it was a propriety kind of thing. I think you can dial 911 and force a connection, but that is about it.

I need to "trim" the steel whip of a two meter antenna, and have not been sucessful in finding an easy way to cut. Tried a vise-grip with its close-in pinchers, and also tried a heavy duty pair of wire cutters, but no go.

What common tool can be used to do this ? This steel whip sure is tough !!

Thanks !!

I use a small rotary grinder to cut a line around the whip and snap it apart in a vice.

I usually use the side of a grinder wheel to cut it off. If I do not have one handy, then I use a triangle shaped file. I often cut it part of the way and then snap it off with the pliers. It usually takes bolt cutters to cut the antenna and then the cut off piece goes out like a bullet.

Need element length measurements. I have the pdf file from the MFJ/ HyGain web site but some of the measurements are difficult to read. Fuzzy scan and vision. It is page 5 in the manual, where it shows the complete layout of the antenna. If someone can make a clear hi-res scan of this one page and email it to me that would be great. It will be most appreciated, 73, Randy, w5kcm

Jim,

It cuts a lot like glass rod. A Dremel is probably the most
civilized way to do it, but I use a small file to cut a shallow notch.
Then, I use a vise or other hard surface to support the long section,
placing the nick right at the edge. A smart blow with a small hammer
will break it off. Use the file to remove the burrs, and off you go.
It requires a bit of practice to get it right, but it works perfectly,
at gets you some appropriate street creds with newer hams.

Please ... treat yourself to your own Dremel. You'll always be glad
you did.

I bought my first Dremel under the Wards Powercraft name in the
1970s. I retrofitted
it with an Allied Radio Motor Speed Control and used it for decades.
A few years ago,
when the bearings began to sound funny, I bought a replacement. I
will NEVER be
without a working Dremel.

I have the additional collets (like the chuck on a drill) that allow
me to use tools
with smaller shafts (like surplus dental drills) and drill bits of any
size, down to a
80 drill bit. I have many dozens of attachments and even a little
Dremel drill
press.

I'll just add the reason -- the common mode current, which is what causes feedline radiation and what we're trying to suppress, is on the outside of the coax. The commonly specified velocity factor (around 0.66 for solid dielectric coax, a bit higher for foamed dielectric) applies to the field inside the coax where the differential mode current flows, not to the outside where the common mode current is. So you use a value near one as Owen says. And it's not at all critical for this purpose.

A standing wave is present on an antenna or radiating feedline -- every half wavelength there's a current null, and offset a quarter wavelength from these are current maxima. For example, there are current nulls at the ends of a half wavelength dipole (or, an even better example, a Yagi parasitic element) and a maximum at the middle. When you insert a balun in a transmission line, it causes a current null at that location, so there'll be a maximum a quarter wavelength down and another minimum a quarter wavelength below that if current is induced by coupling and the length to ground supports that distribution. We want to make that distribution impossible, and inserting the second balun does that.

This is easily observed by modeling, but you have to keep in mind that the actual path the current takes to the Earth along the outside of the coax can be considerably more complicated than most simple models represent. So models can tell you what *can* happen although maybe not necessarily what *is* happening in a given installation.

I've always found that a small set of Bolt Cutters works great....
such as Kobalt 8" or 14" Bolt Cutters $9.98 and $14.98 at Lowe's.

Just one tool to do the job right then and there after checking SWR...

Hmmm you say "ridicuously undersized"..

Why?

have you studied the fusing current of AWG 10?
Have you compared the inductance of various sizes?

Do you know *why* the code only requires AWG 10?

The code requirements are based on actual science, engineering, and test
data, so if the code requires AWG 10, it's probably for a fairly good
reason.

Note that they allow bronze and copper clad steel as well as solid
copper, so clearly, DC resistance isn't what they're worried about.

(hint.. think of mechanical reasons)

Note, especially, that the NEC (NFPA 70) grounding/bonding requirements are NOT for lightning protection. (that's in NFPA 780, not NFPA 70)

> be.

Tom is a bit confused here about the purpose of NEC vs NFPA 780..

The bonding requirements in the NEC are designed to keep the building from burning down in the event of an accidental fault to an energized conductor. The basic requirement is that it carry enough fault current for long enough to trip the overcurrent protection device on the energized conductor.

It's not for lightning protection, per se. (although NEC bonding will, incidentally, provide some degree of protection against induced transients)

I'd also note that AWG 10 wire is more than sufficient to carry a 50kA pulse for the 20 microseconds or so that a lightning stroke lasts without melting.
Using the Onderdonk equation, you can calculate that a AWG16 copper wire will carry about 90kA for a 20 microsecond pulse. AWG10 should be able to carry 4 times that much. AWG6, 10 times, because it scales with cross sectional area.

Having only really paid attention to this recently, I noticed that in Rome (a place with a fair number of thunderstorms), they use fairly small down conductors (AWG 10 or 6, just by eye), and similar for 7 story tall wooden pagodas in Nara, Japan (another place with lots of thunderstorms).

I'm not quite sure where the fashion for 2/0 grounding conductors comes from (maybe Phelps-Dodge has a representative on the NFPA 780 review committee?<grin>)

NFPA 780, like NFPA 70, is a copyrighted document *sold* by NFPA.
However, there *are* online copies of various provenance and age around.
http://www.atmo.arizona.edu/students/courselinks/spring07/atmo589/articles/NFPA_780_2004.pdf

Unfortunately, the bare code doesn't tell you much about the "why" for
various code provisions, so if you're thinking of going "off code" for
one reason or another, you don't have a lot of information to tell you
whether it's a good idea.

There's also some interesting seeming inconsistencies.. NFPA 780
requires a minimum length of a ground rod of 8 feet (4.13.2.1) but also
requires that they extend vertically not less than 10 feet into the
earth (4.13.2.3(A))) The figure makes it clear.. the top of an 8 foot
rod is 2 feet below the surface of the soil.

NFPA 780 says 29 square millimeters for main conductors (6 mm in
diameter or a strip that is 1.3mm thick x 22.3 mm wide).. That's AWG 6
roughly.

There's also a great site by Carl Malamud: publicresource.org that has
all the California Building Codes (including an older rev of the NEC)
although it doesn't have NFPA 780 on it, as far as I know.

Perhaps you could explain why you think it's a bad joke? Do you think a 13 square mm conductor couldn't carry the strike current? (it can)

Or, perhaps, you're thinking that there are some other design criteria that might push one towards a larger conductor (mechanical strength in the face of icing and storms might be one).

IIRC the purpose is to primarily drain off the static charges so the
gnd-cloud potential difference is minimized. A direct strike will
usually just melt whole house wiring, etc. etc.

Marv

> than allowed to build up a differential charge.

This is actually a big problem.. counterfeit rods with UL markings on them, and rods that are too small in diameter or too short to meet NEC requirements.

Electrical Supply places (not the home improvement stores) have had 10 foot rods for a long time.

The NEC has required 8 feet *in the ground* for years and years (at least 20, I think), so the only way to do that with an 8 foot rod is to do your exothermic bond to the rod and completely bury it.

The home improvement stores don't like to stock longer rods because most of the buyers are not "code-aware" and buy on price (hey, an 8 foot rod is cheaper than a 10 foot rod, I'll use that). Besides, for new construction in a lot of places, a rod isn't an acceptable primary grounding means anyway.

And we won't even get into the grounding/bonding practices of satellite dish and Cable TV installers. There's a great website out there with pictures of truly lame installations.

Not true.

The cloud has SO MUCH charge you don't stand a chance of bleeding it off.

Direct strikes are typically around 20 kA, and can be as high as 100kA.
Both can be adequately carried by the usual AWG6 wire, because the
current pulse only lasts a few microseconds.

If you want something beyond code typically we use 00 braided copper
at work for lightning protection on towers. NEC and Polyphaser
recommendations usually work pretty good

Resistance isn't actually a big deal here. It's all about inductance on
that microsecond rise time pulse. And there's not much difference in
inductance between a AWG 6 and 2/0 (it's very weakly dependent on
diameter and strongly dependent on length.. 1 microhenry/meter is a good
estimate, pretty much independent of diameter)

The other problem is that for fast transients, skin effect means that
the AC resistance goes more as the diameter than as the cross sectional
area (hollow tubes work just as well as solid conductors).

So, the net effect is that you need to design for several things:
1) the wire not melting..
2) The wire not breaking from mechanical impact (ladders hitting it,
lawnmowers, etc.
3) The wire not breaking under electromagnetic forces (this is why you
don't want loops and why NFPA 780 says 8" bend radius.. while a 1
microsecond pulse at 10kA won't melt a AWG 10 wire, if it's in a loop,
it will destroy it from EM forces)

You'll see heavier conductors where they have to be able to move (say on a gate or actuated device), not only for mechanical life, but also because the flexible wire is more subject to destruction by EM forces.

Side flash is a consideration, but usually accommodated by making sure your downleads are far from potential victim circuits.

3197. Vertical antenna site tradeoff

On the yard around my house I have two possible spots where to erect a multiband vertical, an HF6V.
On the first spot it is possible to lay down a symmetrical net of radials as long as the antenna is tall, but the antenna will be close to buildings on tree sides, at a distance about two to four times the antenna height. Buildings in Italy are built by rinforced concrete with a lot of steel inside, so I expect there will be some effect to the antenna efficiency and radiation pattern.
On the second spot, the antenna can be more clear of buildings, but the radials pattern is not symmetrical because il is limited to a strip of land wide half the antenna height.
So now is my question: if a tradeoff must be made, what is more important, to have an antenna on the clear or to have the best ground radials system ?
A second question: is it possible to estimate the effect of ground symmetry and of buildings presence on the antenna radiation pattern using antenna simulation software like eznec ?

Thanks to all
Giovanni

That's why I tie everything together. In my case, the ground rods
are minimal.. Just a few copper tubes pounded into the ground
around the base of the mast. None are too deep. But I consider
the ground adequate for the purpose, and it seems to be, being
as I've taken strikes on that mast with no damage to anything.
But I tie that ground into the electrical ground, and also the
plumbing, which I clamp to just a few feet away from the base
of the mast. If all grounds are at the same appx potential, and
the connection to ground is up to par as far as resistance, you
shouldn't see flashing over to other objects. I've never had that
problem here so far. In fact, the connection to ground seems
good enough that strikes to that mast are fairly silent and
only make an electrical arc sound which sounds like throwing
a light bulb onto the ground.
On the other hand, a strike to a poorly grounded object with
high resistance is hugely loud.. Say when it strikes the tree
in the front yard.. It's like a 12 gauge going off. And this

sound is separate from the sonic boom of the strike as
it travels through the air. The sonic boom will come from
overhead and is not local like the actual strike noise at the
object being struck.

better to have the radiating part of the antenna clear. The ground
radials, as long as they are numerous, are less critical

> A second question: is it possible to estimate the effect of ground
> symmetry and of buildings presence on the antenna radiation pattern
> using antenna simulation software like eznec ?

Yes.. to a certain degree

What you can do is put in wires where the building is (like a wireframe
drawing), and then see if there's very much current in those wires, when
the antenna is excited. Small current = little effect.

You can get fancier and try and model the building as a grid of wires
which are very resistive, but I'd start with the simple wireframe and
see what it gives you.

What you're really getting isn't a precise model, but more of a
qualitative assessment of whether there is a problem.

>radials system ?

Hi Giovanni,

The best solution is both - in the clear with a lot of radials. The
next best is to raise your antenna, if you can. After that, and
assuming the antenna is ground mounted; then use as many radials as
you can (12 or more); as long as you can make them (usually as long as
the antenna is tall is enough); filling as much area as you can.

Multiband verticals are usually designed to be up at least 3 meters.
Multiband verticals are usually poor performers on their lowest band.

>A second question: is it possible to estimate the effect of ground
>symmetry and of buildings presence on the antenna radiation pattern
>using antenna simulation software like eznec ?

Yes. Do it one band at a time to keep it simple. You will be able to
see the effect, but it won't really amount to much UNLESS you are
comparing very few radials (2,3 or 4) to 12 or more; or to 120. The
change from 2 to 12 will be more significant than changing from 12 to
120.

You will also see the change in shape of the antenna pattern's
azimuth. It may seem significant, but in reality, it will be
overshadowed by other effects like the proximity of buildings.

Modeling the effect of buildings takes a lot of time and experience.
Antenna modelers are an extension of your design capability, not a
substitute.

Dremels are great for this, but if you use it, get the coated fiberglass cutoff wheel. The other will shatter if the whip shakes at all.

But even simpler... Just file a notch on the whip on either side with a small file. Once you have a notch, use two pairs of vice grips to grab either side of the notch and it should snap easily. Or use a vice and pliers. The trick is to grap the whip as close to the notch as possible and bend quickly. Then file to clean up the break.

With the notch methond, you can snap 1/8" 17-7 stainless fairly easily. You won't snap big stuff, like 1/4" whips, but you're not likely to run into them.

17-7 is common for whips, and by now you've probably discovered how tough it is, and how quickly it ruins cutters and nips!

The problem is that while we might characterise the raw excitation caused by lightning, and use assumptions about the shape, rise and fall times and peak field strength, the response of circuits (such as those that include the down conductor) is quite different, and it is unsafe to assume in the general case that skin effect is fully effective for all or even most of the energy spectrum.

Perhaps that is why some of these standards tend to treat the conductor as having a resistance equal to that implied by just the conductivity (or resistivity) and CSA. It might be conservative, but then standards tend to be so.

Having seen the results of fairly detailed EM modelling of EMP and lightning excitation of major infrastructure, and the effects of some small changes to the model, I wonder a bit about the effectiveness of some measures... but over engineering probably saves the day in a lot of cases.

The real danger with lightning protection is that a half baked approach my give the implementor some comfort, but actually increase the risk of adverse outcome.

The most thorough and consistent practice I have seen is that employed here in mobile phone base stations. Sure, they are occasionally damaged by lightning, but the vast majority of lightning incidents do not cause permanent damage.

Owen

The biggest problem with lightning protection in my area is that the local power company leaves the ground lines coiled up at the bottom of the poles. On about half the poles I've checked.

When they put the new transformer in across the street from my house the crew said they would be back to put in the ground rod. Nope. So I called a friend that si a troubleshooter for the power company about 2 months later and told him about it. "Yup, I'll get somebody right over." No joy 4 years later.

I lost $1500 dollars worth of gear last year because the only decent ground was connected to my radio. And every bit of current that came into the house on the power line exited that direction.

The power companies are likely the worst culprits from my perspective. I have installed more grounds at my house than the rest of the street has. Probably not all to spec, but safer than what wasn't here before.

I also discovered the dictionary definition of replacement cost is not the same one the insurance industry uses. Big surprise.
